**DESCRIPTION**

The MP26029 is a highly integrated, single-cell Li-ion/Li-polymer battery charger IC with thermal regulation. The MP26029 is able to charge the battery by using either an AC adapter (up to 13V) or USB port. The MP26029 also features pre-charge, high-accuracy constant-current charge (CC, up to 1A) and constant-voltage (CV) regulation, charge termination, and auto-recharge.

The MP26029 has input voltage limit function. In case the CC current exceeds the current rating of input power, the MP26029 will decrease the charge current automatically once the input voltage reaches the input voltage limit.

The MP26029 has a NTC pin to monitor the battery temperature via a negative temperature coefficient (NTC) thermistor, once the battery temperature is out of cold/hot window the charging will be suspended.

The MP26029 also has One-time-program (OTP) function to program the parameters like battery full voltage, termination current, input voltage limit, input OVP threshold, thermal regulation threshold and so on.

The MP26029 is available in 6-pin SOT563, 8-pin SOIC8 EP, and 10-pin QFN (3mmx3mm) packages.

**FEATURES**

- Fully Autonomous Charger for Single-Cell Li-Ion/Polymer Batteries
- Programmable Charge Current: 30mA to 1A
- ±0.5% Charging Voltage Accuracy
- 13V Maximum Voltage for the Input Source
- Fully Integrated Power Switches and No External Blocking Diode Required
- Input Voltage Limit Regulation
- Built-In Robust Charging Protection, Including Battery Temperature Monitor and Safety Timer
- Thermal Limiting Regulation On-Chip
- Available in SOT563, SOIC8 EP, and QFN-10 (3mmx3mm) Packages

**APPLICATIONS**

- Smart Handheld Devices
- Digital Cameras, Bluetooth
- Toys

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

NOTES:

1) Exceeding these ratings may damage the device.
2) Per ANSI/ESDA/JEDEC JS-001, all pins
3) Per JESD22-C101, all pins
4) The maximum allowable power dissipation is a function of the maximum junction temperature (T_J (MAX)), the junction-to-ambient thermal resistance (θ_JA), and the ambient temperature (T_A). The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX) - T_A)/θ_JA. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
5) The device is not guaranteed to function outside of its operating conditions.
6) Measured on JESD51-7, 4-layer PCB.

Figure 1: Functional Block Diagram
OPERATION

The MP26029 is a single-cell, Li-ion or Li-polymer battery charger with thermal regulation. The full-function charger features pre-charge (PRE), fast constant-current (CC) and constant-voltage (CV) regulation, charge termination, auto-recharge, and a built-in safety timer.

The IC integrates a charging MOSFET between IN and BATT. See R_{ON,BATT} in the EC table on page 5.

During charging mode, the on-chip charging MOSFET works as a full-featured linear charger with pre-charge, high-accuracy fast constant-current and constant-voltage charge, charge termination, auto-recharge, NTC monitor, safety timer control, and thermal protection. The charge current can be programmed via ISET. The IC limits the charge current when the die temperature exceeds the thermal regulation threshold (120°C).

Power Supply

The internal bias circuit of the IC is powered from the higher voltage of either IN or BATT. When IN or BATT rises above the respective undervoltage lockout (UVLO) threshold, the battery depletion comparator and the charging MOSFET driver are active.

Input Over-Voltage Protection (OVP)

The MP26029 has an input over-voltage protection (OVP) with 6.25V threshold (programmable via OTP). If the input voltage exits the normal input voltage range, the charging MOSFET is turned off immediately.

Battery Charge Profile

The IC provides three main charging phases: pre-charge, fast constant-current charge and constant-voltage charge (see Figure 2).

1. Phase 1 (pre-charge): The IC is able to safely pre-charge the deeply depleted battery until the battery voltage reaches the pre-charge to fast-charge threshold \(V_{BATT\_PRE}\). If \(V_{BATT\_PRE}\) is not reached before the pre-charge timer (1hr) expires, the charge cycle is stopped, and a corresponding timeout fault signal is asserted.

2. Phase 2 (constant-current charge): When the battery voltage exceeds \(V_{BATT\_PRE}\), the IC enters a fast constant-current charge (fast-charge) phase. The fast charge current is programmed via ISET and can be calculated with Equation (1):

\[
I_{CC} (mA) = 3200 \times R_{SET} (k\Omega)^{-1.05} \tag{1}
\]

The charge current can be set from 30mA to 1A for various applications. Floating ISET can disable the charge function.

3. Phase 3 (constant-voltage charge): When the battery voltage rises to the battery regulation voltage \(V_{BATT\_REG}\), the charge mode changes from CC mode to CV mode, and the charge current begins to taper off.

The charge cycle is considered completed when the battery voltage is above the recharge threshold \(V_{RECH}\), and the charge current reaches the battery charge termination current threshold \(I_{TERM}\). If \(I_{TERM}\) is not reached before the safety charge timer expires, the charge cycle stops, and a corresponding timeout fault signal is asserted. See the Safety Timer section on page 13.

The battery charge termination current threshold \(I_{TERM}\) is 10%\(I_{CC}\).

During the entire charging process, the actual charge current may be less than the resistor setting due to the thermal regulation, which reduces the charge current so that the IC junction temperature does not exceed the preset limit.

The following conditions can start a new charge cycle:

- The input power is recycled.
- Auto-recharge kicks in.
- No thermistor fault at NTC.
- No safety timer fault.
- No battery over-voltage.
Automatic Recharge
When the battery is fully charged and charging is terminated, the battery may be discharged due to the system consumption or a self-discharge. When the battery voltage is discharged below the recharge threshold, the IC begins another new charging cycle automatically without having to restart a charging cycle manually.

Battery Over-Voltage Protection (OVP)
The IC is designed with a built-in battery over-voltage limit about 150mV higher than \( V_{BATT\_REG} \). When a battery over-voltage event occurs, the IC suspends the charging immediately and asserts a fault indication at STAT pin.

Floating Charging Voltage
The floating voltage for the constant voltage regulation phase is \( V_{BATT\_REG} \). When \( V_{BATT\_REG} = 4.2V \), it has a ±0.5% accuracy over the ambient temperature range of 0°C to +50°C. When the battery is removed, the BATT voltage is between \( V_{BATT\_REG} - V_{RECH} \) and \( V_{BATT\_REG} \).

Input Voltage Limit Regulation
If the input power source is not sufficient for supporting the charge current, the input voltage decreases. As the input voltage reaches the input voltage limit threshold, the charge current is reduced to prevent the input voltage from dropping further.

Thermal Regulation and Thermal Shutdown
The IC monitors the internal junction temperature continuously to maximize power delivery and prevent the chip from overheating. When the internal junction temperature reaches the preset limit of \( T_{J\_REG} (120°C) \), the IC reduces the charge current to prevent higher power dissipation.

When the junction temperature reaches 150°C, the charging MOSFET is turned off.

Negative Temperature Coefficient (NTC) Temperature Sensor
NTC allows the IC to sense the ambient temperature using the thermistor typically available in the battery pack to ensure a safe operating environment of the chip. A resistor with an appropriate value should be connected from IN to NTC, and the thermistor should be connected from NTC to ground. The voltage on NTC is determined by the resistor divider, whose divide ratio depends on the battery temperature. The IC sets a pre-determined upper and lower bound of the divide ratio internally for NTC cold and NTC hot.

Once the NTC voltage exits the divide ratio (the temperature is outside the safe operating range), the IC stops charging and reports it on the status pin. Charging resumes automatically after the temperature enters the safe range again.
Safety Timer
The IC provides both a pre-charge and a fast-charge safety timer to prevent an extended charging cycle due to abnormal battery conditions. The pre-charge safety timer is one hour when the battery voltage is lower than \( V_{\text{BATT,PRE}} \). The fast-charge safety timer (seven hours) begins when the battery enters fast charging.

The safety timer is reset at the beginning of a new charging cycle.

Charge Enable Control
The MP26029 can reuse ISET pin to disable or enable charging by floating ISET pin or not. A recommended circuit is shown in Figure 4. Logic high will enable the charging and logic low will disable the charging.

Status Indication (\( \text{STAT} \))
The IC has a hardware status output pin (\( \text{STAT} \)). The status of \( \text{STAT} \) in different cases is shown in Table 1.

Figure 3: Charging Process
APPLICATION INFORMATION

Setting the Charge Current

A resistor (R\text{SET}) connected from ISET to GND sets the charge current (I\text{CC}). The relationship between the charge current and setting resistor is established in Figure 4.

![Figure 4: Charge Current vs. R\text{SET} Resistance](image-url)

For example, if the typical I\text{CC} is 1A, then R\text{SET} is calculated as 3.01kΩ. The tolerance of the I\text{CC} setting is ±10%. If a minimum or maximum charge current is required, first the typical value should be calculated according to the tolerance. Afterward, calculate the resistor according to Equation (1). Table 2 shows the calculated charging current with different resistances.

Selecting a Resistor for the NTC Sensor

NTC uses a resistor divider from the input source (IN) to sense the ambient temperature. The two resistors, R\text{T1} and R\text{T2}, allow the high temperature limit and low temperature limit to be programmed independently (see Figure 5).

![Figure 5: NTC Function Block](image-url)

For a given NTC thermistor, set the NTC window by selecting appropriate R\text{T1} and R\text{T2} values with Equation (2) and Equation (3):

\[
R_{T2} = \frac{(V_{TH\_COLD} - V_{TH\_HOT}) \times R_{NTCH} \times R_{NTCL}}{(V_{TH\_HOT} - V_{TH\_COLD}) \times R_{NTCL} - (V_{TH\_COLD} - V_{TH\_HOT}) \times R_{NTCH}}
\]

(2)

\[
R_{T1} = \frac{1 - V_{TH\_COLD}}{V_{TH\_COLD}} \times \left( R_{T2} / R_{NTCL} \right)
\]

(3)

Where R\text{NTCH} is the value of the NTC resistor at the high end of the required temperature operation range, and R\text{NTCL} is the NTC resistor value at a low temperature.

The R\text{T1} and R\text{T2} values depend on the type of NTC resistor used. For example, for the thermistor NCP18XH103, R\text{NTCL} is 27.219kΩ at 0°C, and R\text{NTCH} is 4.161kΩ at 50°C.

Equation (2) and Equation (3) can be used to calculate R\text{T1} = 9.25kΩ and R\text{T2} = 32.31kΩ, assuming that the NTC window is between 0°C and 50°C and using the V\text{TH\_HOT} and V\text{TH\_COLD} values from the EC table.

Selecting the Input Capacitor

An input capacitor is required for stability. Connect a minimum 4.7µF capacitor between IN and GND for stable operation. There can be more output capacitance than input as long as the input is at least 4.7µF.
Selecting the BATT to GND Capacitor
A capacitor from BATT to GND is also necessary in the MP26029. A >20µF ceramic capacitor (dielectric types X5R or X7R) is suitable for the MP26029 application circuit.

PCB Layout Guidelines
Place the external capacitors as close to the IC as possible to ensure the smallest input inductance and the ground impedance.
