DESCRIPTION

The MP2234 is a high-frequency, synchronous, rectified, step-down, switch-mode converter with built-in power MOSFETs. It offers a very compact solution to achieve a 2A continuous output current with excellent load and line regulation over a wide input supply range. The MP2234 has synchronous mode operation for higher efficiency over the output current load range.

Current-mode operation provides fast transient response and eases loop stabilization.

Full protection features include over-current protection and thermal shut down.

The MP2234 requires a minimal number of readily-available standard external components, and is available in a space-saving 8-pin TSOT23 package.

FEATURES

- Wide 4.5V-to-16V Operating Input Range
- 100mΩ/40mΩ Low R_{DS(ON)} Internal Power MOSFETs
- High-Efficiency Synchronous Mode Operation
- Fixed 800kHz Switching Frequency
- Synchronizes from a 300kHz-to-2MHz External Clock
- Power-Save Mode at Light Load
- External Soft-Start
- OCP Protection and Hiccup
- Thermal Shutdown
- Output Adjustable from 0.8V
- Available in an 8-pin TSOT-23 Package

APPLICATIONS

- Notebook Systems and I/O Power
- Digital Set-Top Boxes
- Flat-Panel Television and Monitors
- Distributed Power Systems

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Quality Assurance. “MPS” and “The Future of Analog IC Technology” are Registered Trademarks of Monolithic Power Systems, Inc.

PACKAGING REFERENCE

ABSOLUTE MAXIMUM RATINGS (1)

- **V<sub>IN</sub>**: -0.3V to 17V
- **V<sub>SW</sub>**: -0.3V (-5V for <10ns) to 17V (19V for <10ns)
- **V<sub>BST</sub>**: -0.3V to 6V
- **V<sub>EN/SYNC</sub>**: -0.3V to 5V
- **All Other Pins**: -0.3V to 6V (2)

Continuous Power Dissipation (T<sub>A</sub> = +25°C) (3)

- Junction Temperature: 150°C
- Lead Temperature: 260°C
- Storage Temperature: -65°C to 150°C

Recommended Operating Conditions (4)

- Supply Voltage **V<sub>IN</sub>**: 4.5V to 16V
- Output Voltage **V<sub>OUT</sub>**: 0.8V to **V<sub>IN</sub>** x 90%
- Operating Junction Temp. (T<sub>J</sub>): -40°C to +125°C

Thermal Resistance (5) θ<sub>JA</sub> θ<sub>JC</sub>

- TSOT-23-8: 100... 55... °C/W

Notes:

1) Exceeding these ratings may damage the device.
2) About the details of EN pin’s ABS MAX rating, please refer to Page 9. Enable/SYNC control section.
3) The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub> (MAX), the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub> (MAX) = (T<sub>J</sub> (MAX) - T<sub>A</sub>) / θ<sub>JA</sub>. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
4) The device is not guaranteed to function outside of its operating conditions.
5) Measured on JESD51-7, 4-layer PCB.
## ELECTRICAL CHARACTERISTICS (6)

\( \text{V}_{\text{IN}} = 12\text{V}, \; \text{T}_A = 25^\circ\text{C}, \) unless otherwise noted.

FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram
OPERATION

The MP2234 is a high-frequency, synchronous, rectified, step-down, switch-mode converter with built-in power MOSFETs. It offers a very compact solution that achieves a 2A continuous output current with excellent load and line regulation over a wide input supply range.

The MP2234 operates in a fixed-frequency, peak-current-control mode to regulate the output voltage. An internal clock initiates a PWM cycle. The integrated high-side power MOSFET turns on and remains on until the current reaches the value set by the COMP voltage. When the power switch is off, it remains off until the next clock cycle starts. If, within 95% of one PWM period, the current in the power MOSFET does not reach the value set by the COMP value, the power MOSFET is forced off.

Internal Regulator
A 5V internal regulator powers most of the internal circuits. This regulator takes \( V_{\text{IN}} \) and operates in the full \( V_{\text{IN}} \) range. When \( V_{\text{IN}} \) exceeds 5.0V, the output of the regulator is in full regulation. When \( V_{\text{IN}} \) is less than 5.0V, the output decreases, and the part requires a 0.1\( \mu \)F ceramic decoupling capacitor.

Error Amplifier
The error amplifier compares the FB pin voltage to the internal 0.807V reference (\( V_{\text{REF}} \)) and outputs a current proportional to the difference between the two. This output current then charges or discharges the internal compensation network to form the COMP voltage, which controls the power MOSFET current. The optimized internal compensation network minimizes the external component counts and simplifies the control loop design.

Enable/SYNC Control
EN/SYNC is a digital control pin that turns the regulator on and off. Drive EN high to turn on the regulator; drive it low to turn it off. An internal 1M\( \Omega \) resistor from EN/SYNC to GND allows EN/SYNC to be floated to shut down the chip.

The EN pin is clamped internally using a 6.5V series-Zener-diode as shown in Figure 2. Connecting the EN input pin through a pullup resistor to the voltage on the IN pin limits the EN input current to less than 100\( \mu \)A.

For example, with 12V connected to IN, \( R_{\text{PULLUP}} \geq (12V - 6.5V) ÷ 100\mu A = 55k\Omega \).

Connecting the EN pin is directly to a voltage source without any pullup resistor requires limiting the amplitude of the voltage source to \( \leq 6V \) to prevent damage to the Zener diode.

For external clock synchronization, connect a clock with a frequency range between 300kHz and 2MHz 2ms after the output voltage is set: The internal clock rising edge will synchronize with the external clock rising edge. Select an external clock signal with a pulse width less than 1.2\( \mu \)s.

Under-Voltage Lockout (UVLO)
The MP2234 has under-voltage lock-out protection (UVLO). When the VCC voltage exceeds the UVLO rising threshold voltage, the MP2234 powers up. It shuts off when the VCC voltage drops below the UVLO falling threshold voltage. This is non-latch protection.

The MP2234 is disabled when the input voltage falls below 3.25V. If an application requires a higher under-voltage lockout (UVLO) threshold, use the EN pin as shown in Figure 3 to adjust the input voltage UVLO by using two external resistors. For best results, set the UVLO falling threshold (VSTOP) above 4.5V using the enable resistors. Set the rising threshold (VSTART) to provide enough hysteresis to allow for any input supply variations.
**Soft-Start**

Adjust the soft-start time by connecting a capacitor from SS pin to ground. When the soft-start begins, an internal 11μA current source charges the external capacitor. During soft-start, the soft-start capacitor connects to the non-inverting input of the error amplifier. The soft-start period continues until the voltage on the soft-start capacitor exceeds the 0.8V reference. Then the non-inverting amplifier uses the reference voltage as the input. Use the following equation to calculate the soft-start time:

\[
 t_{SS} = \frac{0.8V \times C_{ss}(nF)}{11\mu A}
\]

**Power Save Mode for Light Load Condition**

The MP2234 has AAM (Advanced Asynchronous Modulation) power save mode for light load. The AAM voltage is set at 0.6V internally. Under the heavy load condition, the \( V_{COMP} \) is higher than \( V_{AAM} \). When clock goes high, the high-side power MOSFET turns on and remains on until \( V_{ILsense} \) reaches the value set by the COMP voltage. The internal clock resets every time when \( V_{COMP} \) is higher than \( V_{AAM} \).

Under the light load condition, the value of \( V_{COMP} \) is low. When \( V_{COMP} \) is less than \( V_{AAM} \) and \( V_{FB} \) is less than \( V_{REF} \), \( V_{COMP} \) ramps up until it exceeds \( V_{AAM} \). During this time, the internal clock is blocked, thus the MP2234 skips some pulses for PFM (Pulse Frequency Modulation) mode and achieves the light load power save.

**Over-Current-Protection and Hiccup**

The MP2234 has a cycle-by-cycle over-current limit when the inductor current peak value exceeds the set current limit threshold. Meanwhile, the output voltage drops until \( V_{FB} \) is below the Under-Voltage (UV) threshold—typically 50% below the reference. Once UV is triggered, the MP2234 enters hiccup mode to periodically restart the part. This protection mode is especially useful when the output is dead-shorted to ground, and greatly reduces the average short circuit current to alleviate thermal issues and protect the regulator. The MP2234 exits the hiccup mode once the over-current condition is removed.

**Thermal Shutdown**

Thermal shutdown prevents the chip from operating at exceedingly high temperatures. When the silicon die reaches temperatures that exceed 150°C, it shuts down the whole chip. When the temperature drops below its lower threshold, typically 130°C, the chip is enabled again.

**Floating Driver and Bootstrap Charging**

An external bootstrap capacitor powers the floating power MOSFET driver. This floating driver has its own UVLO protection. This UVLO’s rising threshold is 2.2V with a hysteresis of 150mV. The bootstrap capacitor voltage is regulated internally by \( V_{IN} \) through D1, M1, R3, C4, L1 and C2 (Figure 5). If \( (V_{IN} - V_{SW}) \) exceeds 5V, U1 will regulate M1 to maintain a 5V BST voltage across C4. A 20Ω resistor placed between SW and BST cap. is strongly recommended to reduce SW spike voltage.
Figure 5: Internal Bootstrap Charging Circuit

Startup and Shutdown

If both $V_{IN}$ and $V_{EN}$ exceed their respective thresholds, the chip starts. The reference block starts first, generating stable reference voltage and currents, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuitries.

Three events can shut down the chip: $V_{EN}$ low, $V_{IN}$ low, and thermal shutdown. During the shutdown procedure, the signaling path is first blocked to avoid any fault triggering. The COMP voltage and the internal supply rail are then pulled down. The floating driver is not subject to this shutdown command.
APPLICATION INFORMATION

Setting the Output Voltage
The external resistor divider sets the output voltage (see Typical Application on page 1).

Choose R1 around 40kΩ for V_{OUT}>1.2V then R2 is then given by:

\[
R_2 = \frac{R_1}{V_{OUT} - 1}\]

The T-Type resistor R5 is used to control the bandwidth of control loop which will be introduced below.

Control Loop Compensation
MP2234 employs peak current mode control for easy compensation and fast transient response. To simplify the compensation design and minimize external components, MP2234 integrates internal compensation. Figure 6 shows an equivalent model for the device control loop.

![Figure 6: Equivalent Control Loop Model](image)

The device power stage can be approximated to a voltage controlled current source (duty cycle modulator) supplying current to the output capacitor and load resistor. The control (V_C) to output (V_{OUT}) transfer function is shown as below:

\[
\frac{V_{OUT}}{V_C} = A_{DC} \times \frac{1 + \frac{s}{2\pi f_{Z1}}}{1 + \frac{s}{2\pi f_{P1}}}
\]

\[
A_{DC} = \frac{R_1}{R_i}
\]

\[
f_{Z1} = \frac{1}{2\pi R_{ESR} C_{OUT}}
\]

\[
f_{P1} = \frac{1}{2\pi R_i C_{OUT}}
\]

Where A_{DC} is the DC gain of power stage, R_L is the load resistance, R_i is the current sense resistance (R_i=0.22Ω). R_{ESR} is the equivalent series resistance of output capacitor. C_{OUT} is the output capacitance.

MP2234 uses voltage type amplifier for the feedback error amplifier and integrates compensation to ease the system design. The output to control transfer function is given by:

\[
\frac{V_C}{V_{OUT}} = -A_{EA} \frac{(1 + \frac{s}{2\pi f_{Z2}})(1 + \frac{s}{2\pi f_{Z3}})}{s(1 + \frac{s}{2\pi f_{P2}})(1 + \frac{s}{2\pi f_{P3}})}
\]

\[
A_{EA} = \frac{R_2}{(C_Z + C_p)(R_1 R_T + R_1 R_2 + R_2 R_1)}
\]

\[
f_{Z2} = \frac{1}{2\pi R_Z C_Z}
\]

\[
f_{Z3} = \frac{1}{2\pi R_i C_F}
\]

\[
f_{P2} = \frac{1}{2\pi R_Z C_P}
\]

\[
f_{P3} = \frac{1}{2\pi (R_i // R_2 // R_T) C_Z}
\]

Where R_1, R_2 are the feedback resistors, R_T is the T-type resistor between feedback resistor divider and FB pin. C_F is the type III compensation feed forward capacitor. R_Z, C_Z and C_P are internal compensation resistor and capacitors.

The goal of compensation design is to shape the converter transfer function to get a desired loop gain. The system crossover frequency where the feedback loop has the unity gain is important. Lower crossover frequency results in slower line
and load transient responses, while higher crossover frequency could cause system instability. A good rule of thumb is to set the crossover frequency below one-tenth of the switching frequency.

To optimize the compensation components, the following procedure can be used.

1. Choose high-side feedback resistor $R_1$ and calculate the value of low-side resistor $R_2$ according to desired output voltage. Suggest choosing $R_1$ around 40kΩ for >1.2V output condition.

2. Choose the T-Type resistor $R_T$ to set the desired crossover frequency. Determine the $R_T$ value by the following equation:

$$R_T = \frac{V_{FB} \times R_Z}{V_{OUT} \times R_1 \times 2\pi \times f_C \times C_{OUT}} - \frac{R_1 \times R_2}{R_1 + R_2}$$

$R_Z$ is the internal compensation resistor, which equals to 300kΩ. $f_C$ is the desired crossover frequency which is typically one tenth of the switching frequency. $R_i$ is the current sense resistance, 0.22Ω.

3. Choose feed forward capacitor $C_F$ to achieve sufficient phase margin especially for large output inductor condition. In theory there is no need to add type III zero for peak current mode control, but in real circuit there are some parasitic capacitors or filters internal which induces poles into the control loop. Fortunately, those poles are locating at high frequency range which won’t affect the step 2 bandwidth calculation while it affects the phase margin. For applications with typical inductor values (<4.7µH), setting the compensation zero, $f_23$ (formed by $R_1$ and $C_F$) around 1.5 times of crossover frequency $f_C$. Then the $C_F$ value can be calculated by following equation:

$$C_F = \frac{1}{3\pi \times R_1 \times f_C}$$

If electrolytic capacitor is used or the output capacitor has large ESR, the feed forward capacitor $C_F$ is not needed any more since there is already one ESR zero in the loop.

If large output inductor is used, like 22µH, the phase margin will decrease a lot due to the half switching frequency pole moves towards crossover frequency. In this condition, it’s suggested increasing feed forward capacitor value of $C_F$ to get enough phase margins while it’s better to keep the feed forward zero frequency higher than half of crossover frequency.

![Figure 7: T-Type Network](image_url)

Table 1 lists the recommended resistors and compensation values for common output voltages (refer to Figure 7).

**Selecting the Inductor**

Use a 1µH-to-22µH inductor with a DC current rating of at least 25% percent higher than the maximum load current for most applications. For highest efficiency, use an inductor with a DC resistance less than 15mΩ. For most designs, the inductance value can be derived from the following equation.

$$L_i = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{OSC}}$$

Where $\Delta I_L$ is the inductor ripple current.
Choose the inductor ripple current to be approximately 30% of the maximum load current. The maximum inductor peak current is:

\[ I_{\text{L(MAX)}} = I_{\text{LOAD}} + \frac{\Delta I_{\text{L}}}{2} \]

Use a larger inductor for improved efficiency under light-load conditions—below 100mA.

**Selecting the Input Capacitor**

The input current to the step-down converter is discontinuous, therefore requires a capacitor to supply the AC current to the step-down converter while maintaining the DC input voltage. Use low ESR capacitors for the best performance. Use ceramic capacitors with X5R or X7R dielectrics for best results because of their low ESR and small temperature coefficients. For most applications, use a 22µF capacitor.

Since \( C_1 \) absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated by:

\[ I_{C_1} = I_{\text{LOAD}} \times \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}}} \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \]

The worse case condition occurs at \( V_{\text{IN}} = 2V_{\text{OUT}} \), where:

\[ I_{C_1} = \frac{I_{\text{LOAD}}}{2} \]

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum or ceramic. When using electrolytic or tantalum capacitors, add a small, high quality ceramic capacitor (e.g. 0.1µF) placed as close to the IC as possible. When using ceramic capacitors, make sure that they have enough capacitance to provide sufficient charge to prevent excessive voltage ripple at input. The input voltage ripple caused by capacitance can be estimated as:

\[ \Delta V_{\text{IN}} = \frac{I_{\text{LOAD}}}{f_s \times C_1} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \]

**Selecting the Output Capacitor**

The output capacitor (\( C_2 \)) maintains the DC output voltage. Use ceramic, tantalum, or low-ESR electrolytic capacitors. For best results, use low ESR capacitors to keep the output voltage ripple low. The output voltage ripple can be estimated as:

\[ \Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{8 \times f_s \times L_1 \times C_2} \times \frac{1}{R_{\text{ESR}}} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \]

Where \( L_1 \) is the inductor value and \( R_{\text{ESR}} \) is the equivalent series resistance (ESR) value of the output capacitor.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency, and the capacitance causes the majority of the output voltage ripple. For simplification, the output voltage ripple can be estimated as:

\[ \Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{8 \times f_s \times L_1 \times C_2} \times \frac{1}{R_{\text{ESR}}} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \]

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated as:

\[ \Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{8 \times f_s \times L_1 \times C_2} \times \frac{1}{R_{\text{ESR}}} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \]

The characteristics of the output capacitor also affect the stability of the regulation system. The MP2234 can be optimized for a wide range of capacitance and ESR values.
External Bootstrap Diode

An external bootstrap diode can enhance the efficiency of the regulator given the following conditions:

- $V_{OUT}$ is 5V or 3.3V; and
- Duty cycle is high: $D = \frac{V_{OUT}}{V_{IN}} > 65\%$

In these cases, add an external BST diode from the VCC pin to BST pin, as shown in Figure 8.

![Figure 8: Optional External Bootstrap Diode to Enhance Efficiency](image)

The recommended external BST diode is IN4148, and the BST capacitor value is 0.1µF to 1µF.
PC Board Layout

PCB layout is very important to achieve stable operation especially for VCC capacitor and input capacitor placement. For best results, follow these guidelines:

1. Use large ground plane directly connected to GND pin. Add vias near the GND pin if the bottom layer is ground plane.

2. Place the VCC capacitor to VCC pin and GND pin as close as possible. Make the trace length of VCC pin-VCC capacitor anode-VCC capacitor cathode-chip GND pin as short as possible.

3. Place the ceramic input capacitor close to IN and GND pins. Keep the connection of input capacitor and IN pin as short and wide as possible.

4. Route SW, BST away from sensitive analog areas such as FB. It's not recommended to route SW, BST trace under chip's bottom side.

5. Place the T-type feedback resistor R5 close to chip to ensure the trace which connects to FB pin as short as possible.

Notes:

8) The recommended layout is based on the Figure 8 Typical Application circuit on the next page.

Design Example

Below is a design example following the application guidelines for the specifications:

PACKAGE INFORMATION

TSOT23-8

NOTE:
1) ALL DIMENSIONS ARE IN MILLIMETERS.
2) PACKAGE LENGTH DOES NOT INCLUDE MOLD FLASH, PROTRUSION OR GATE BURR.
3) PACKAGE WIDTH DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSION.
4) LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.10 MILLIMETERS MAX.
5) JEDEC REFERENCE IS MO-193, VARIATION BA.
6) DRAWING IS NOT TO SCALE.
7) PIN 1 IS LOWER LEFT PIN WHEN READING TOP MARK FROM LEFT TO RIGHT, (SEE EXAMPLE TOP MARK)
