DESCRIPTION

The MP2690 is a highly integrated, flexible, switch-mode battery charger with system power-path management and is designed for single-cell Li-ion or Li-polymer battery use in a wide range of applications.

The IC can operate in both charge mode and boost mode to allow for full system and battery power management.

The IC has an integrated IN-to-SYS pass-through path to pass the input voltage to the system. The pass-through path has built-in over-voltage and over-current protection and has a higher priority over the charging path.

When the input power is present, the device operates in charge mode. The MP2690 detects the battery voltage automatically and charges the battery in three phases: trickle current, constant current, and constant voltage. Other features include charge termination and auto-recharge. The MP2690 also integrates both input current limit and input voltage regulation to manage input power and meet the priority of the system power demand.

In the absence of an input source, the IC switches to boost mode through PB to power SYS from the battery. In boost mode, OLIM programs the output current limit, and the IC turns off at light load automatically. The IC also uses output short-circuit protection to disconnect the battery from the load completely in the event of a short-circuit fault. The MP2690 resumes normal operation once the short-circuit fault is removed.

The 4-LED driver is integrated for voltage-based fuel gauge indication. Together with torch-light control, the MP2690 provides an all-in-one solution for power banks and similar applications without an external micro-controller.

The MP2690 is available in a 26-pin QFN (4mmx4mm) package.

FEATURES

- Up to 14V Sustainable Input Voltage
- 4.65V to 6V Operating Input Voltage Range
- Power Management Function, Integrated Input Current Limit, Input Voltage Regulation
- Up to 2.5A Programmable Charge Current
- Trickle-Charge Function
- Selectable 4.2V/4.35V/4.45V Charge Voltage with 0.5% Accuracy
- 4-LED Driver for Battery Fuel Gauge Indication
- Automatic Turn-Off at Light Load
- Input Source Detection
- Output Source Signaling
- Torch-Light Control
- Negative Temperature Coefficient Pin for Battery Temperature Monitoring
- Programmable Timer Back-Up Protection
- Thermal Regulation and Thermal Shutdown
- Internal Battery Reverse Leakage Blocking
- Integrated Over-Voltage Protection (OVP) and Over-Current Protection (OCP) for Pass-Through Path
- Reverse Boost Operation Mode for System Power
- Up to 2.1A Programmable Output Current Limit for Boost Mode
- Integrated Short-Circuit Protection (SCP) and Output Over-Voltage Protection for Boost Mode

APPLICATIONS

- Sub-Battery Applications
- Power-Bank Applications for Smart Phones
- Tablets and Other Portable Devices

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. “MPS” and “The Future of Analog IC Technology” are registered trademarks of Monolithic Power Systems, Inc.

Storage temperature ............... -65°C to +150°C

Recommended Operating Conditions (3)
Supply voltage (V_IN) ................. 4.65V to +6V
I_IN ........................................... Up to 2.7A
I_SYS .......................................... Up to 2.1A
I_CHG ........................................ Up to 2.5A
V_BATT ....................................... Up to 4.45V
Operating junction temp. (T_J) ....... -40°C to +125°C

Thermal Resistance (4) θ_JA θ_JC
QFN-26 (4mmx4mm) .............. 44 9 ....°C/W

NOTES:
1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_JA, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX) - T_A)/θ_JA. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.

OPERATION

The MP2690 is a highly integrated, flexible, switch-mode battery charger with system power-path management designed for single-cell Li-ion or Li-polymer battery use in a wide range of applications. Depending on the status of the input, the IC can operate in three different modes: charge mode, boost mode, and sleep mode.

In charge mode, the IC can work with a single-cell Li-ion or Li-polymer battery. In boost mode, the IC boosts the battery voltage to $V_{SYS}$ to power higher voltage system rails. In sleep mode, both charging and boost operations are disabled, and the device enters a power-saving mode to help reduce overall power consumption. The IC monitors $V_{IN}$ to allow smooth transitions between different modes of operation.

VCC Power Supply

The MP2690 has an external VCC power supply. VCC is powered by the highest voltage level out of $V_{SYS}$, $V_{BATT}$, and $V_{IN} - 0.7V$. An external capacitor is required to bypass VCC to GND. When VCC is higher than 2.2V, the internal control circuit is activated.

Charge Mode Operation

Charge Cycle

(Trickle Charge $\rightarrow$ CC Charge $\rightarrow$ CV Charge)

In charge mode, the IC uses five control loops to regulate the input current, input voltage, charge current, charge voltage, and device junction temperature. The IC charges the battery in three phases: trickle current (TC), constant current (CC), and constant voltage (CV).

When charge operation is enabled, all five loops are active, but only one dictates the IC behavior. A typical battery charge profile is shown in Figure 9a. The charger stays in TC charge mode until the battery voltage reaches a TC-to-CC threshold. Otherwise, the charger enters CC charge mode.

When the battery voltage rises to the CV mode threshold, the charger operates in constant voltage mode. Figure 9b shows a typical charge profile when the input current limit loop dominates during the CC charge mode. In this case, the charger maximizes the charging current due to the switching-mode charging solution, resulting in charging that is faster than a traditional linear charging solution.

\[
I_{CHG}(A) = \frac{1500}{R_{SET}(k\Omega) \times RS1(m\Omega)}
\]  

(1)

Auto-Recharge

Once the battery charge cycle is completed, the charger remains off. During this time, the system load may consume battery power, or the battery may self-discharge. To ensure that the battery does not go into depletion, a new charge cycle begins automatically when the battery voltage falls below the auto-recharge threshold and the input power is present. The timer resets when the auto-recharge cycle begins.

If the input power restarts during the off-state after the battery is fully charged, the charge cycle starts, and the timer resets regardless of what the battery voltage is.

Charge Current Setting

The external sense resistors (RS1 and $R_{ISET}$) program the battery charge current ($I_{CHG}$). Select $R_{ISET}$ based on RS1.

To optimize the transfer efficiency, RS1 is recommended to be 10mΩ. The relationship between $R_{ISET}$ and $I_{CHG}$ is shown in Equation (1):
Battery Over-Voltage Protection (OVP)
The IC has battery over-voltage protection (OVP). If the battery voltage exceeds the battery over-voltage threshold (103.5% of the battery’s full voltage), charging is disabled. Under this condition, an internal 5kΩ dummy load draws a small current from BATT to reduce the battery voltage and protect the battery.

Timer Operation in Charge Mode
The IC uses an internal timer to terminate the charging. The timer remains active during the charging process. An external capacitor between TMR and GND programs the charge cycle duration. If charging remains in TC mode beyond the trickle-charge time \( \tau_{\text{TRICKLE}_\text{TMR}} \), charging is terminated. For the MP2690, the charge current in TC mode is fixed at 265mA, and the sense resistor (RS1) is set to 10mΩ. The length of the trickle-charge period can be determined with Equation (2):

\[
\tau_{\text{TRICKLE}_\text{TMR}} = 17 \text{mins} \times \frac{C_{\text{TMR}} (\mu F)}{0.1 \mu F}
\]

(2)

The maximum total charge time can be calculated with Equation (3):

\[
\tau_{\text{TOTAL}_\text{TMR}} = 7.55 \text{Hours} \times \frac{C_{\text{TMR}} (\mu F)}{0.1 \mu F} \times \frac{1 \text{A}}{I_{\text{CHG}}(A) + 0.1}
\]

(3)

Negative Temperature Coefficient (NTC) Input for Battery Temperature Monitoring
The IC has a built-in NTC resistance window comparator, which allows the IC to monitor the battery temperature via the battery-integrated thermistor during both charge and boost modes. Connect an appropriate resistor from VNTC to NTC and connect the thermistor from NTC to GND. The resistor divider determines the NTC voltage depending on the battery temperature. If the NTC voltage falls outside of the NTC window, the IC stops charging. The operation then restarts if the temperature goes back into the NTC window range. Please refer to the Application Information section on page 33 for the appropriate resistor selection.

VNTO Power Supply
The MP2690 has NTC protection in both boost mode and charge mode. To allow NTC protection in both boost mode and charge mode and to minimize the battery leakage current in sleep mode, the MP2690 uses a dedicated power supply pin for the pull-up voltage for the NTC protection function block. In boost mode and charge mode, VNTC is connected to VCC internally by a switch. In sleep mode, VNTC is disconnected from VCC to minimize the battery leakage current (see Figure 10).

Figure 10: NTC Protection Block

Input DP1/DM1 USB Detection and Input Current Limit
Power devices (PDs) are able to draw current from the USB ports in personal computers to charge their batteries. If the portable device is attached to a USB host of the hub, then the USB specification requires the portable device to draw a limited current (usually 500mA). When the device is attached to a charging port, it is allowed to draw more than 1.5A.

The IC features input source detection to determine the input current limit according to the input source (USB or adapter) (see Figure 11).
When the input source plugs in, the IC starts DP1/DM1 detection. DP1/DM1 detection has two steps: data contact detection (DCD) and primary detection. DCD uses a current source to detect when the data pins have made contact during an attach event. The protocol for data contact detection is as follows:

1. The power device (PD) detects if VIN is asserted.
2. The PD turns on DP, IDP_SRC, and the DM pull-down resistor for 40ms.
3. The PD waits for the DP line to be low.
4. The PD turns off IDP_SRC and the DM pull-down resistor when the DP line is detected to be low, or when the 40ms timer expires.

DCD allows the PD to start primary detection once the data pins have made contact. Once the data contact is detected, the IC jumps to the primary detection immediately. If the data contact is not detected, the IC jumps to the primary detection automatically after 300ms from the beginning of the DCD.

Primary detection is used to distinguish between the USB host (or SDP) and different types of charging ports.

During primary detection, the PD turns on VDP_SRC on DP1 and IDM_SINK on DM1. If the portable device is attached to a USB host, DM1 is low. If the power device is attached to CDP, DCP, or another dedicated charging port, DM1 remains high.

To be compatible with different capacities of the input source, the input current limit is recommended to be set using Table 2 if a 5V input is requested.

### Table 2: Input Current Limit Setting

<table>
<thead>
<tr>
<th>DP1/DM1 Detection</th>
<th>IN_LMT</th>

<td>Floating</td>
<td>500mA</td>
</tr>
<tr>
<td>SDP</td>
<td>500mA</td>
</tr>
<tr>
<td>CDP or DCP</td>
<td>Set through RILIM</td>
</tr>
</tbody>
</table>

The USB detection runs once VIN is detected and is independent of the charge enable status. After the DP1/DM1 detection is done, the IC sets the input current limit as shown in Table 2.

When the detection algorithm is completed, the DP1 and DM1 signal lines enter a high-Z state with approximately 4pF of capacitive load.

### External Input Current Limit Setting

The IC has a dedicated pin used to program the input current limit when CDP or DCP is detected. The current at ILIM is a fraction of the input current. The ILIM voltage indicates the average input current of the switching regulator as determined by the resistor value between ILIM and GND. As the input current approaches the programmed input current limit, the charge current is reduced to give priority to the system power.

The input current limit threshold can be determined with Equation (4):

\[
I_{\text{ILIM}} = \frac{40(k\Omega)}{R_{\text{ILIM}}(k\Omega)}(A)
\]

### Input Voltage Regulation in Charge Mode

In charge mode, if the input power source is not sufficient for supporting both the charge current and the system load current, the input voltage decreases. As the input voltage internally approaches the 4.65V input voltage regulation threshold preset, the charge current is reduced to give priority to the system power and maintain proper regulation of the input voltage.
Integrated Over-Current Protection and Over-Voltage Protection for Pass-Through Path
The IC has an integrated IN-to-SYS pass-through path to allow direct connection of the input voltage to the system. Therefore, the IC monitors both the input current and voltage continuously. In the event of an overload, the charge current is reduced to ensure priority of the system power requirements.

The IC also features input over-current and over-voltage protection for the IN-to-SYS pass-through path.

Input Over-Current Protection (OCP)
When the total input current exceeds 5A, Q2 is controlled linearly to regulate the current (see Figure 12). If the current continues to exceed 5A after 200μs of blanking time, Q2 is turned off. In the event of the input current exceeding 7A, Q2 is turned off almost instantaneously and without any blanking time. This is done to protect both Q1 and Q2.

Input Over-Voltage Protection (OVP)
The IC has a built-in over-voltage threshold (V_{IN,OVP}). When the input voltage is higher than V_{IN,OVP}, an invalid input power source is detected by the IC. At this time, the IN-to-SYS pass-through path is turned off to prevent connecting to the wrong adapter.

Battery Short Protection
In charge mode, the MP2690 uses two inherent current-limit thresholds due to a peak-current-control strategy. CC and CV modes have a peak-current-limit threshold of 7A, while TC mode has a current-limit threshold of 4A. Therefore, the current-limit threshold decreases to 4A when the battery voltage drops below the TC threshold. The switching frequency also decreases when the BATT voltage drops to 40% of the charge-full voltage.

Thermal Foldback Function
The IC implements thermal protection to prevent thermal damage to the IC and the surrounding components. An internal thermal sense and feedback loop decreases the programmed charge current automatically when the die temperature reaches 120°C. This function is called the charge-current-thermal foldback. This function protects against thermal damage and sets the charge current based on requirements rather than worst-case conditions while ensuring safe operation. The part also includes thermal shutdown protection, where the charging process is stopped if the junction temperature rises to 150°C.

Non-Sync Operation Mode
During charging mode, the IC monitors the total input current flowing from IN to SYS continuously. When the input current is lower than 170mA, the low-side switch operates as a non-synchronous MOSFET.

Constant Off-Time Control for Large Duty Charging Operation
The IC has a built-in 600kHz frequency oscillator for the switching frequency. Unlike a traditional fixed-frequency, peak-current control, the IC features a constant-off time control to support a constant current charge even when the input voltage is very close to the battery voltage. The IC compares the high-side MOSFET sense current with the comp level continuously (see Figure 13). If the sense current does not reach the comp level within the original switching period, the next clock is delayed until the sense current reaches the comp level. As a result, the duty cycle is able to be extended as long as possible.

Indication for Fault Flag in Charge Mode
The MP2690 is designed with distinct indication separating the charging fault from the normal operation. At the charging fault, including INOVP, BOVP, and NTC fault, the four LED pins blink with a 1Hz frequency simultaneously (see Table 3).

#### Boost Mode Operation

**Low-Voltage Start-Up**

The minimum battery voltage required to start up the circuit in boost mode is 2.9V. Initially, when \( V_{SYS} \) is less than \( V_{BATT} \), the IC works in down mode. In this mode, the synchronous P-FET stops switching and its gate connects to \( V_{BATT} \) statically. The P-FET stays off for as long as the voltage across the parasitic \( C_{DS} \) (\( V_{SW} \)) is lower than \( V_{BATT} \). When the voltage across \( C_{DS} \) exceeds \( V_{BATT} \), the synchronous P-FET enters linear mode, allowing the inductor current to decrease and flow into SYS. Once \( V_{SYS} \) exceeds \( V_{BATT} \), the P-FET gate is released and the normal closed-loop PWM operation is initiated. In boost mode, the battery voltage can drop as low as 2.5V without affecting circuit operation.

**SYS Disconnect and Inrush Limiting**

The IC can achieve true output disconnect by eliminating body diode conduction of the internal P-FET rectifier. \( V_{SYS} \) can go to 0V during shutdown, drawing no current from the input source. It also allows for inrush current limiting at start-up, minimizing surge currents from the input supply. To optimize the benefits of the output disconnect, avoid connecting an external Schottky diode between SW and SYS.

Board layout is extremely critical for minimizing voltage overshoot at SW due to stray inductance. Keep the output filter capacitor as close to SYS as possible and use very low ESR/ESL ceramic capacitors tied to a good ground plane.

**Boost Output Voltage Setting**

In boost mode, the IC programs the output voltage internally according to the load connected to SYS (5.1V or 5.2V) and provides built-in output over-voltage protection (OVP) to protect the device and other components against damage when \( V_{SYS} \) goes beyond 6V. Once output over-voltage occurs, the IC turns off the boost converter. When the voltage on \( V_{SYS} \) drops to a normal level, the boost converter restarts again when PB is set from high to low for more than 1.5ms.

**Boost Output Current Limiting**

The IC integrates a programmable output current limit function in boost mode. If the boost output current exceeds this programmable limit, the output current is limited at this level and the SYS voltage begins to drop down. OLIMIT programs the current limit threshold up to 2.1A, per Equation (5):

\[
I_{OLIMIT}(A) = \frac{1500}{R_{OLIMIT}(k\Omega) \times RS1(m\Omega)}
\]
The MP2690 can operate in CC mode when the current limit is reached, and $V_{IN}$ does not drop to the down mode threshold ($V_{BATT} + 100\text{mV}$) (see Figure 14).

**Figure 14: Boost Output U-I Curve**

The MP2690 not only has CC mode during the charging process, but also has CC mode operation in boost mode for various applications.

**SYS to BATT Block Protection**

When there is no $V_{IN}$ and the boost mode is not on, the part is in sleep mode. The HS switch implements the body switch function, which connects the body diode of the switch to the high-voltage side of SW and SYS, which blocks the external voltage on SYS from flooding into the battery.

**SYS Output Over-Current Protection (OCP)**
The IC integrates a three-phase output over-current protection.

1. **Phase one (boost mode output current limit):** When the output current exceeds the programmed output current limit, the output constant current loop controls the output current, the output current remains at its limit ($I_{OLIM}$), and $V_{SYS}$ decreases.

2. **Phase two (down mode):** When $V_{SYS}$ drops below $V_{BATT} + 100\text{mV}$, and the output current loop remains in control, the boost converter enters down mode and shuts down after $120\mu\text{s}$ of blanking time.

3. **Phase three (short-circuit mode):** When $V_{SYS}$ drops below $4.0\text{V}$ ($2\text{V}$ during boost soft start), the boost converter shuts down immediately once the inductor current hits the foldback peak-current limit of the low-side N-FET. The boost converter can also recover automatically after a $1\text{ms}$ deglitch period.

**Thermal Shutdown Protection**
The thermal shutdown protection is also active in boost mode. Once the junction temperature rises higher than $150\text{°C}$, the IC enters thermal shutdown and does not resume normal operation until the junction temperature drops below $120\text{°C}$.

**Automatic Off at Light Load**
The boost turns off automatically if the load current at BATT is below the typical $75\text{mA}$ value for 16 seconds.

The MP2690 also features a long-push action on PB to shut down the boost manually. A low push on PB longer than 2.5 seconds is defined as a long push (see Figure 14 for PB action).

**Automatic Output DP2/DM2 Signaling**
In boost mode, the IC sets the DP2/DM2 signal based on the load applied on USB2. In pass-through mode, DP2 and DM2 are set according to DP1/DM1 detection results.

In boost mode, DM2/DP2 are set based on three types of signals: DM2/DP2 separately biased with a $2.7\text{V}$ voltage signal (default), DM2/DP2 shorted, and DM2/DP2 shorted with a $1.2\text{V}$ bias.

In pass-through mode, DM2/DP2 are connected together if the dedicated charger ports are detected, and pulled down to ground separately with a $15k\Omega$ resistor if SDP is identified.

**Torch Control**
If the internal torch drive FET is off when PB is pulled from high to low for more than $1.5\text{ms}$ within one second, the drive FET is turned on. Conversely, if the torch drive FET is on, the drive FET is turned off.

Once the torch light is turned on, the automatic-off function is blocked.

**PB Control**
PB is used to control the enable of boost mode. Pull PB from high to low for more than $1.5\text{ms}$ to enable boost mode; pull PB from high to low for $2.5\text{s}$ to disable boost mode.
Automatic On when Load is Applied

The boost turns on automatically when PB is pulled from high to low for more than 1.5ms, or when the load is plugged in to USB2 using the PB control.

To detect the USB load plug-in, the RC network is connected to the USB port shield floating in the PCB. Once the USB load is inserted, the USB connector shield is grounded through the USB load. So a short pulse (high to low for more than 1.5ms) is generated in PB, resulting in the start of boost.

An RC network can also be connected in VBUS of the USB output port. During load insertion, the load input cap generates a high-to-low pulse for more than 1.5ms to start the boost (see Figure 15). The circuit in the dash frame is the automatic load detection circuit. M2 is used to decouple the USB port from the VSYS cap (C2, Csys), and M1 is used to drive M2.

Once a phone is plugged in, the voltage at CUSB is pulled down because the input cap inside the phone is far lower than CUSB. So the falling edge is delivered to PB to enable boost automatically.

M3 is used to cut off PB to and from the USB port when boost is turned on. The PB state is not affected by the spec of the inserted load of the USB port. Choose M3 with a low turn-on threshold (-0.7V is recommended) which can ensure that it is fully on when the load is inserted and that its on resistance does not cause too much of a voltage drop.

4-LED Driver for Voltage-Based Fuel Gauge

The IC provides 4-LED drivers for a voltage-based fuel gauge. The driver is connected to an internal open-drain FET. The 4-LED indication values are shown in Table 4.

The LED threshold can be programmed using a fuse. Each threshold can be adjusted from 150mV to 200mV with 50mV steps from their default value.

The LED threshold is also adjusted automatically based on the VBAT_REG setting. The VOREG difference is considered to be offset for LED thresholds.

During voltage measurement, the battery impedance (50mΩ) should be compensated based on the battery current to get a precise battery voltage for fuel gauge indication.

Indication for Fault Flag in Boost Mode

To minimize the power consumption of the battery, the indication is active once PB is short-pushed in normal discharge operation, and turns off after five seconds automatically.

APPLICATION INFORMATION

Setting the Charge Current in Charge Mode

In charge mode, both the external sense resistor (RS1) and the resistor (R_{SET}) connect to ISET to set the charge current (I_{CHG}) of the MP2690 (see the Typical Application circuit on page 2). Given the expected I_{CHG} and RS1 values, R_{SET} can be calculated with Equation (6):

\[ I_{CHG} = \frac{1500}{R_{SET}(k\Omega) \times RS1(m\Omega)} \]  

For example, if I_{CHG} = 2.5A and RS1 = 10mΩ, then R_{SET} = 60kΩ.

Given a 10mΩ RS1, Table 6 lists the expected R_{SET} values for the typical charge current.

Setting the Input Current Limit in Charge Mode

In charge mode, connect a resistor from ILIM to AGND to program the input current limit if a dedicated charger (CDP or DCP) is detected. The relationship between the input current limit and setting resistor is shown in Equation (7):

\[ I_{ILIM} = \frac{40(k\Omega)}{R_{ILIM}(k\Omega)}(A) \]  

R_{ILIM} must exceed 14.7kΩ so that I_{IN,ILIM} is in the range of 0A to 2.7A.

NTC Function in Charge Mode

An internal resistor divider sets the low temperature threshold (V_{TL}) and high temperature threshold (V_{TH}) at 66.6% of V_{SYS} and 35% of V_{SYS}, respectively (see Figure 16). For a given NTC thermistor, select an appropriate R_{T1} and R_{T2} to set the NTC window with Equation (8) and Equation (9):

\[ \frac{V_{TH}}{V_{SYS}} = \frac{R_{T2}/R_{NTC,Hot}}{R_{T1} + R_{T2}/R_{NTC,Hot}} = TH = 35\% \]  

Where R_{NTC,Hot} is the value of the NTC resistor at the upper bound of its operating temperature range, and R_{NTC,Cold} is its lower bound.

The two resistors R_{T1} and R_{T2} determine the upper and lower temperature limits independently. This flexibility allows the IC to operate with most NTC resistors for different temperature range requirements. Calculate R_{T1} and R_{T2} with Equation (10) and Equation (11):

\[ R_{T1} = \frac{R_{NTC,Hot} \times R_{NTC,Cold} \times (TL - TH)}{TH \times TL \times (R_{NTC,Cold} - R_{NTC,Hot})} \]  

\[ R_{T2} = \frac{(TL - TH) \times R_{NTC,Cold} \times R_{NTC,Hot}}{(1 - TL) \times TH \times R_{NTC,Cold} \times (1 - TH) \times TL \times R_{NTC,Hot}} \]  

For example, the NCP18XH103 thermistor has the following electrical characteristics:

- At 0°C, R_{NTC,Cold} = 27.445kΩ
- At 50°C, R_{NTC,Hot} = 4.1601kΩ

Based on Equation (17) and Equation (18), an R_{T1} value of 6.65kΩ and an R_{T2} value of 25.63kΩ are suitable for an NTC window between 0°C and 50°C. Approximate values are R_{T1} = 6.65kΩ and R_{T2} = 25.5kΩ.

If no external NTC is available, connect R_{T1} and R_{T2} to keep the voltage on NTC within the valid NTC window (e.g.: R_{T1} = R_{T2} = 10kΩ).

![Figure 16: NTC Function Block](image-url)
Setting the Output Current Limit in Boost Mode

In boost mode, connect a resistor from OLIM to AGND to program the output current limit. The relationship between the output current limit and setting resistor is shown in Equation (12):

$$I_{OLIM} = \frac{1500}{R_{OLIM} \times RS1}$$  \hspace{1cm} (12)$$

The output current limit of the boost can be programmed up to 2.1A.

Given a 10mΩ RS1, Table 7 lists the expected $R_{OLIM}$ values for the typical output current limit.

Selecting the Inductor

The inductor selection trades off between cost, size, and efficiency. A lower inductance value corresponds with a smaller size, but results in higher current ripples, higher magnetic hysteretic losses, and higher output capacitances. However, a higher inductance value benefits from lower ripple currents and smaller output filter capacitors, but results in a higher inductor DC resistance (DCR) loss. Choose an inductor that does not saturate under the worst-case load condition.

In charge mode, the MP2690 works as a buck converter. The required inductance can be estimated with Equation (13):

$$L = \frac{V_{IN} - V_{BATT}}{\Delta I_{L_{MAX}}} \times \frac{V_{BATT}}{V_{IN} \times f_s}$$  \hspace{1cm} (13)$$

Where $V_{IN}$ is the typical input voltage, $V_{BATT}$ is the CC charge threshold, $f_s$ is the switching frequency, and $\Delta I_{L_{MAX}}$ is the maximum peak-to-peak inductor current, which is usually designed at 30% - 40% of the CC charge current.

With a typical 5V input voltage, if there is a 35% inductor current ripple at the corner point between the trickle charge and the CC charge ($V_{BATT} = 3V, I_{CHG} = 2.5A$), then the inductance is 2.2µH.

In boost mode, the MP2690 works as a boost converter. The required inductance value can be calculated with Equation (14), Equation (15), and Equation (16):

$$L = \frac{V_{BATT} \times (V_{SYS} - V_{BATT})}{V_{SYS} \times f_S \times \Delta I_{L_{MAX}}}$$  \hspace{1cm} (14)$$

$$\Delta I_{L_{MAX}} = (30\% - 40\%) \times I_{BATT(MAX)}$$  \hspace{1cm} (15)$$

$$I_{BATT(MAX)} = \frac{V_{SYS} \times I_{SYS(MAX)}}{V_{BATT \times \eta}}$$  \hspace{1cm} (16)$$

Where $V_{BATT}$ is the minimum battery voltage, $f_{SW}$ is the switching frequency, and $\Delta I_{L_{MAX}}$ is the peak-to-peak inductor ripple current (approximately 30% of the maximum battery current ($I_{BATT(MAX)}$), $I_{SYS(MAX)}$ is the system current, and $\eta$ is the efficiency.

The worst case occurs if the battery voltage is 3V, there is a 30% inductor current ripple, and the typical system voltage is $V_{SYS} = 5V$. Then, the inductance is 1.5µH when the efficiency is 90%.

For best results, use an inductor with an inductance of 2.2µH with a DC current rating no lower than the peak current of the MOSFET. For higher efficiency, minimize the inductor’s DC resistance.

Selecting the Input Capacitor ($C_{IN}$)

The input capacitor ($C_{IN}$) reduces both the surge current drawn from the input and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent the high-frequency switching current from passing to the input. Ceramic capacitors with X7R dielectrics are recommended because of their low ESR and small temperature coefficients. For most applications, a 22µF capacitor is sufficient.

Selecting the System Capacitor ($C_{SYS}$)

Select the system capacitor ($C_{SYS}$) based on the demand of the system current ripple. In charge mode, $C_{SYS}$ acts as the input capacitor of the buck converter. The input current ripple can be calculated with Equation (17):

$$I_{RMS_{MAX}} = I_{SYS_{MAX}} \times \frac{\sqrt{V_{TC} \times (V_{IN_{MAX} - V_{TC}})}}{V_{IN_{MAX}}}$$  \hspace{1cm} (17)$$
In boost mode, $C_{\text{SYS}}$ is the output capacitor of the boost converter. $C_{\text{SYS}}$ keeps the system voltage ripple small and ensures feedback loop stability. The system current ripple can be calculated with Equation (18):

$$I_{\text{RMS_MAX}} = I_{\text{SYS_MAX}} \times \sqrt{V_{\text{TC}} \times (V_{\text{SYS_MAX}} - V_{\text{TC}}) / V_{\text{SYS_MAX}}}$$ (18)

Since the input voltage is passed to the system directly, $V_{\text{IN_MAX}}$ is equal to $V_{\text{SYS_MAX}}$, and both charge mode and boost mode have the same system current ripple.

When $I_{\text{CC_MAX}}$ equals 2A, $V_{\text{IN}}$ equals 3V, $V_{\text{IN_MAX}}$ equals 6V, and the maximum ripple current is 1A. Select the system capacitors based on the ripple-current temperature rise, not exceeding 10°C. For best results, use low ESR ceramic capacitors with X7R dielectrics and small temperature coefficients. For most applications, use three 22µF capacitors.

**Selecting the Battery Capacitor ($C_{\text{BATT}}$)**

$C_{\text{BATT}}$ is in parallel with the battery to absorb the high-frequency switching ripple current. In charge mode, the capacitor ($C_{\text{BATT}}$) is the output capacitor of the buck converter. The output voltage ripple is then calculated with Equation (19):

$$\Delta V_{\text{BATT}} = \frac{1 - V_{\text{BATT}} / V_{\text{SYS}}}{8 \times C_{\text{BATT}} \times f_{\text{SW}}^2 \times L}$$ (19)

In boost mode, $C_{\text{BATT}}$ is the input capacitor of the boost converter. The input voltage ripple is the same as the output voltage ripple from Equation (19).

Both charge mode and boost mode have the same battery voltage ripple. $C_{\text{BATT}}$ can be calculated with Equation (20):

$$C_{\text{BATT}} = \frac{1 - V_{\text{TC}} / V_{\text{SYS_MAX}}}{8 \times \Delta V_{\text{BATT_MAX}} \times f_{\text{SW}}^2 \times L}$$ (20)

To guarantee ±0.5% BATT voltage accuracy, the maximum BATT voltage ripple must not exceed 0.5% (e.g.: 0.1%). The worst case occurs at the minimum battery voltage of the CC charge with the maximum input voltage. For example, $V_{\text{SYS_MAX}} = 6V$, $V_{\text{CC_MIN}} = V_{\text{TC}} = 3V$, $L = 2.2\mu H$, $f_{\text{S}} = 600kHz$, $\Delta V_{\text{BATT_MAX}} = 0.1\%$, and $C_{\text{BATT}}$ is 22µF.

A 22µF ceramic capacitor with X7R dielectrics is sufficient.

**PCB Layout Guidelines**

Efficient PCB layout is critical for meeting specified noise, efficiency, and stability requirements. The following design considerations can improve circuit performance:

1. Route the power stage adjacent to their grounds.
2. Minimize the high-side switching node (SW, inductor) trace lengths in the high-current paths.
3. Keep the switching node short and away from all small control signals, especially the feedback network.
4. Place the input capacitor as close to VIN and PGND as possible.
5. Place the local power input capacitors connected from SYS to PGND as close to the IC as possible.
6. Place the output inductor close to the IC.
7. Connect the output capacitor between the inductor and PGND of the IC.
8. Connect the power pads for VIN, SYS, SW, BATT, and PGND to as many coppers planes on the board as possible for high-current applications.

   *This improves thermal performance because the board conducts heat away from the IC.*

9. Connect a ground plane directly to the return of all components through vias (e.g.: two vias per capacitor for power-stage capacitors, and one via per capacitor for small-signal components).

   *A star ground design approach is typically used to keep circuit block currents isolated (power-signal/control-signal), which reduces noise-coupling and ground-bounce issues. A single ground plane for this design provides good results.*

10. Place ISET, OLIM, and ILIM resistors very close to their respective IC pins.
