

DESCRIPTION

The MP3385A is a step-up controller with four regulated current channels designed to drive WLED arrays for mid- and large-sized LCD panel backlighting applications.

The MP3385A uses peak-current mode and PWM control architecture for system loop regulation. The MP3385A drives an external MOSFET to boost up the output voltage from a 4.5V-to-33V input supply.

The MP3385A employs an I²C digital interface that can flexibly set operation and protection modes, including dimming mode, dimming current and dimming ratio, OCP, OVP, LED short protection threshold, and switching frequency. For easy application use and board debugging, the MP3385A detects and disables the unused LED strings automatically during start-up to avoid charging the output to the OVP threshold.

The MP3385A achieves 1.8% current matching between each string. The low regulation voltage on the LED current sources improves efficiency and reduces power loss to achieve a higher current output.

The MP3385A supports analog, PWM, and combined analog and PWM dimming modes to meet different application requirements. Full protection features include over-current protection (OCP), over-temperature protection (OTP), under-voltage protection (UVP), over-voltage protection (OVP), LED short/open protection, and inductor/diode short protection.

The MP3385A is available in a QFN-20 (4mmx4mm) package.

FEATURES

- 4-String, Max 300mA/String WLED Driver
- 4.5V to 33V Input Voltage Range
- 80V ABS Rating for Each String
- 1.8% Current Matching Accuracy for Each String
- Unused Channel Auto-Detection Function during Start-Up
- 100kHz-900kHz Programmable Switching Frequency
- Multiple Dimming Modes Selected by I²C Interface
 - Direct PWM Dimming Mode
 - Internal Fixed 23kHz PWM Dimming Mode by I²C
 - Analog Dimming Mode by Input Pulse
 - Internal Analog Dimming Mode by I²C
 - Mixed Dimming Mode by Input Pulse
 - Internal Mixed Dimming Mode by I²C
- 2%-100% Programmable Full Scale Current with 8-Bit Resolution
- 0%-100% LED Dimming Range with 10-Bit Resolution for Internal Dimming Mode
- Cascading Capability with a Single Power Source
- 18V to 80V Over-Voltage Protection (OVP), 2V/Step
- 0.15V to 0.5V Latch-Off/Recoverable Over-Current Protection (OCP) Threshold, 50mV/Step
- Recoverable Thermal Shutdown Protection

APPLICATIONS

- Desktop LCD Flat Panel Displays
- All-in-One PCs
- 2D/3D LCD TVs

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

Operating junction temp.....	-40°C to +125°C

Thermal Resistance ⁽⁴⁾	θ_{JA}	θ_{JC}	
QFN-20 (4mmx4mm).....	42.....	9....	°C/W

NOTES:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX)-T_A)/θ_{JA}. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.

PIN FUNCTIONS

Package Pin #	Name	Description
1	DRV	Step-up converter power switch gate output. DRV drives the external power N-channel MOSFET device. Connect a resistor (e.g.: 10Ω) to DRV.
2	VCC	Internal 6V linear regulator output. VCC provides a power supply for the external MOSFET switch gate driver and internal control circuitry. Bypass VCC to GND with a ceramic capacitor.
3	EN	Enable control input. A voltage greater than 1.5V turns the part on. A voltage less than 0.6V turns the part off. Do not float EN.
4	VIN	Supply input. VIN must be bypassed locally.
5	PWM	PWM input signal for brightness control. Ensure that the PWM amplitude voltage level is higher than V_{PWM_HI} , and the low-level voltage is lower than V_{PWM_LO} . The input PWM signal frequency determines the LED current dimming ratio when the MP3385A works in direct PWM dimming mode. For external analog and mixed dimming modes, the PWM pulse is filtered to a DC signal by an LPF capacitor, and the LED current is proportional to the input PWM duty. If PWM is floated, weakly pull PWM to GND internally.
6	SCL	I²C clock input.
7	SDA	I²C data input.
8	FT	Fault indication output. FT is an open drain during normal operation. FT is pulled low during a fault condition.
9	LPF	Low-pass filter output for analog dimming with PWM input. A capacitor is connected between LPF and GND when the part operates in external PWM input analog dimming or mixed dimming mode. Remove the LPF capacitor when the part operates in direct PWM dimming mode.
10	OSC	Switching frequency set. Connect a resistor (R_{OSC}) between OSC and GND to set the step-up converter switching frequency. The clock frequency is proportional to the current sourced from OSC. There is a 100~900kHz switching frequency selected by the I ² C interface when connected to a 100kΩ resistor at OSC.
11	COMP	Step-up converter compensation. COMP compensates for the regulation control loop. Connect a ceramic capacitor and resistor from COMP to GND.
12	ISSET	LED current set. Tie a current-setting resistor from ISET to ground to program the current in each LED string.
13	LED4	LED string 4 current input. LED4 is the open-drain output of an internal dimming control switch. Connect the LED string 4 cathode to LED4.
14	LED3	LED string 3 current input. LED3 is the open-drain output of an internal dimming control switch. Connect the LED string 3 cathode to LED3.
15	PGND	Power ground.
16	LED2	LED string 2 current input. LED2 is the open-drain output of an internal dimming control switch. Connect the LED string 2 cathode to LED2.
17	LED1	LED string 1 current input. LED1 is the open-drain output of an internal dimming control switch. Connect the LED string 1 cathode to LED1.
18	OVP	Output over-voltage protection.
19	IS	Current sense input. During normal operation, IS senses the voltage across the external inductor current-sensing resistor (R_{SENSE}) for peak-current-mode control. IS also limits the inductor current during every switching cycle. If the MP3385A is used for cascading applications, tie IS of the slave chip to GND. Do not float IS.
20	AGND	Signal ground.

BLOCK DIAGRAM

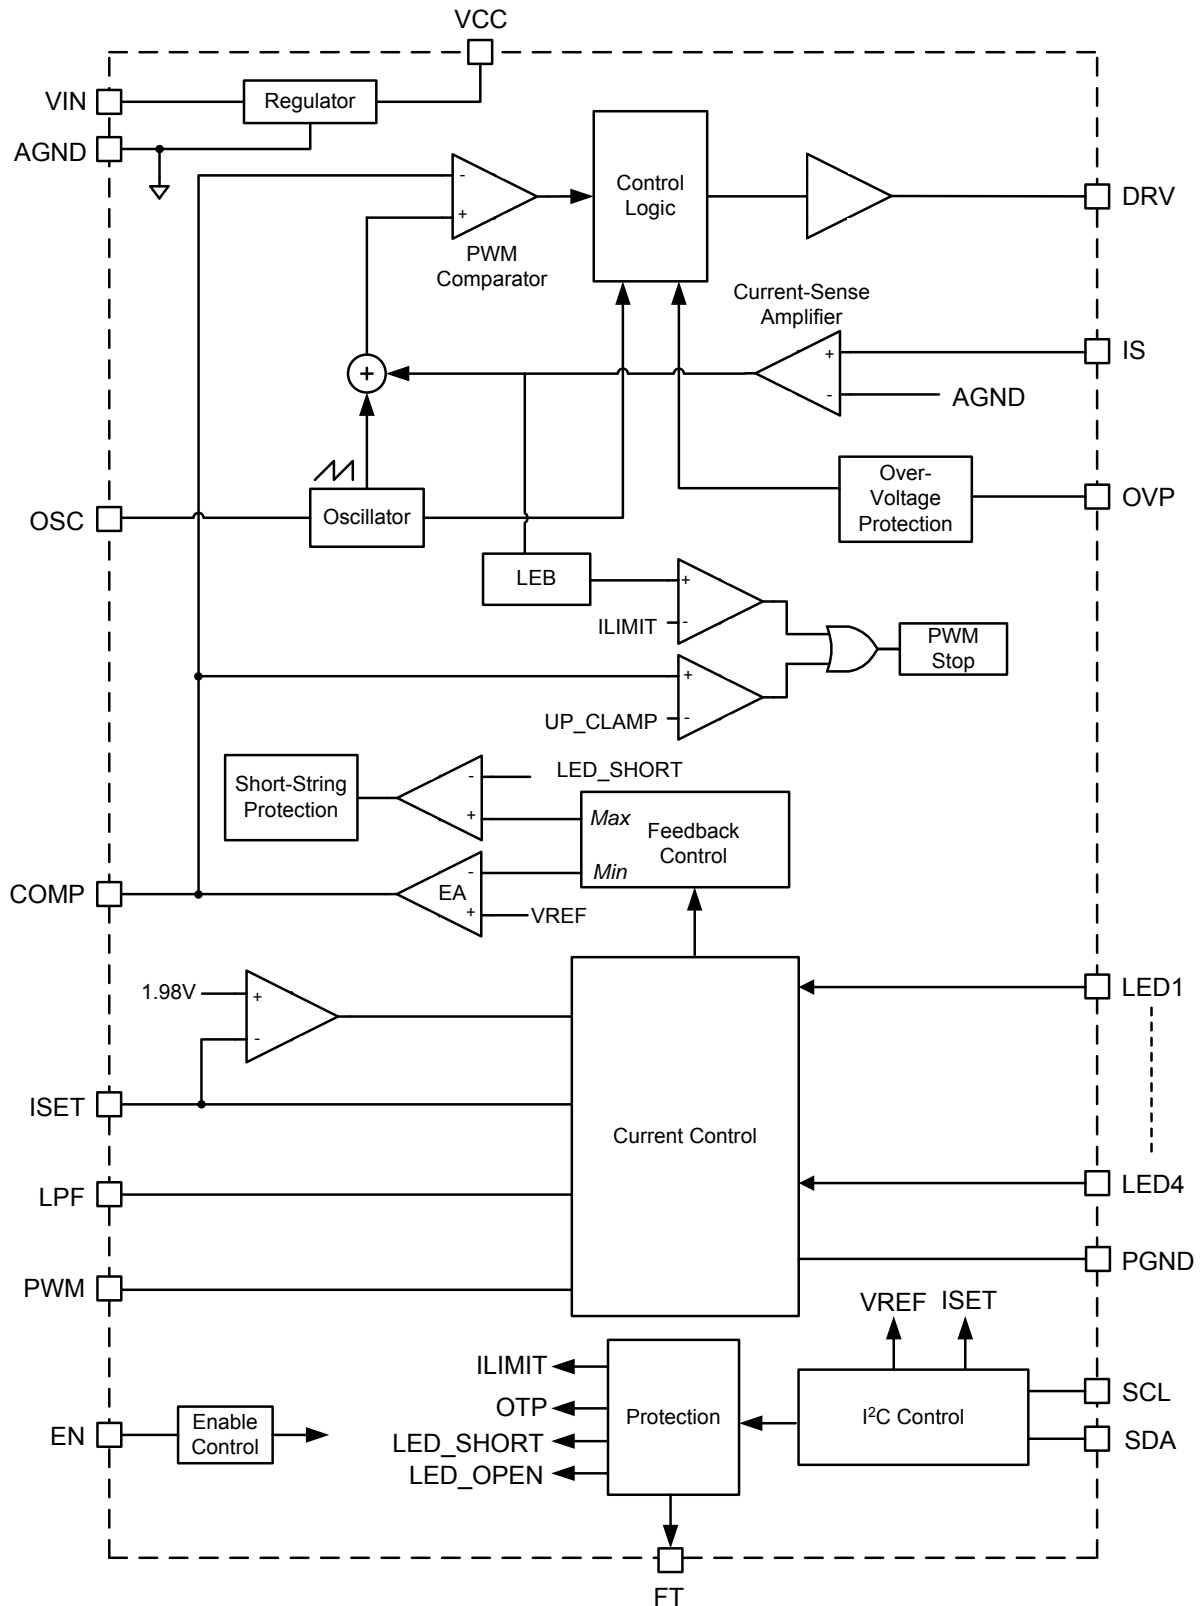

Figure 2: Functional Block Diagram

OPERATION

The MP3385A employs a programmable, constant-frequency, peak-current mode, step-up converter with four regulated current channels to drive an array of four strings of white LEDs. The MP3385A has an I²C interface for easy communication that sets the operation modes flexibly.

Internal 6V Regulator

The MP3385A includes an internal linear regulator (VCC). When VIN is greater than 6.5V, the regulator outputs a 6V power supply to the external MOSFET switch gate driver and the internal control circuitry. The VCC voltage drops to 0V when the chip shuts down. The MP3385A features under-voltage lockout (UVLO), in which the chip is disabled until VCC exceeds the UVLO threshold. The UVLO hysteresis is approximately 340mV.

System Start-Up

When enabled, the MP3385A checks the topology connection first. The chip monitors the over-voltage protection (OVP) pin to determine if the Schottky diode is connected or if the boost output is shorted to GND. An OVP voltage higher than 2.5V allows the chip to switch normally. Otherwise, switching is disabled. The MP3385A checks additional safety limits including LED open/short protection, UVLO, over-temperature protection (OTP), and over-current protection (OCP) after passing the OVP test. If all the protection tests pass, the chip begins boosting the step-up converter with an internal soft start.

Step-Up Converter

At the beginning of each switching cycle, the internal clock turns on the external MOSFET. In normal operation, the minimum turn-on time is around 150ns. A stabilizing ramp is added to the output of the current sense amplifier to prevent sub-harmonic oscillations for duty cycles greater than 50%. This result is fed into the PWM comparator. When the summed voltage reaches the output voltage of the error amplifier (V_{COMP}), the external MOSFET turns off.

The output voltage of the internal error amplifier is an amplified signal of the difference between the reference voltage and the feedback voltage.

The converter chooses the lowest active LEDX voltage automatically to provide a high-enough bus voltage to power all of the LED arrays.

If the feedback voltage drops below the reference, the output of the error amplifier increases. This results in more current flowing through the MOSFET, increasing the power delivered to the output. This forms a closed loop that regulates the output voltage.

Under light-load operation, especially in the case of $V_{OUT} \approx V_{IN}$, the converter runs in pulse-skipping mode where the MOSFET turns on for a minimum on time, and then the converter discharges the power to the output for the remaining period. The external MOSFET remains off until the output voltage needs to be boosted again.

Dimming Control

The MP3385A provides flexible dimming methods according to the dimming mode settings below.

1) PWM Dimming Mode

MODE bits = 00b. The LED current duty cycle directly follows the PWM input signal duty cycle when INTERFACE = 0. The IC works in internal PWM dimming mode, and the LED current duty cycle is set by the internal registers 03H and 04H when INTERFACE = 1. The internal dimming frequency is fixed at 23kHz.

2) Analog Dimming Mode

MODE bits = 01b. The LED current amplitude follows the duty cycle of the input PWM signal when INTERFACE = 0. The IC works in internal analog dimming mode (the LED current amplitude follows the internal register value of 03H and 04H) if INTERFACE = 1.

3) Mixed Dimming Mode

There are two transfer points from analog to PWM dimming (25% or 50%) set by the I²C interface.

If the MODE bits = 10b when the dimming duty cycle is larger than the 25% threshold, the IC works in analog dimming mode. Otherwise, the IC works in PWM dimming mode, and the LED current follows the PWM ratio. If the MODE bits = 11b when the dimming duty cycle is larger than the 50% threshold, the IC works in analog dimming mode. Otherwise, the IC works in PWM dimming mode.

In mixed dimming mode, when INTERFACE = 0, the LED current amplitude is proportional to the ratio of the external PWM signal if the duty cycle of PWM is larger than the transfer point (25% or 50%). The LED current amplitude is fixed to 100% brightness while the LED current duty is equal to the input PWM ratio (if the duty cycle of PWM is lower than the transfer point). When INTERFACE = 1, the LED current amplitude and the duty cycle are set by registers 03H and 04H.

Regardless of the INTERFACE setting (1 or 0), the LED current frequency is fixed at 23kHz in mixed dimming mode when the duty cycle is lower than the transfer point (25% or 50%).

In analog and mixed dimming mode, to avoid noise at the small dimming ratio, the IC turns off the current sources if the current is less than 1.2% times the full scale current.

For external analog and mixed dimming modes, the minimum pulse width of the PWM signal is limited to 2μs to avoid noise interruption.

Operation Switching Frequency

The operation frequency of the converter can be changed by the OSC resistor and the FS0-3 bit in register 01H. The switching frequency covers 100kHz to 900kHz through the I²C register bits when a 100kΩ resistor is connected to OSC. This optimizes the size of the external components and system efficiency.

Open-String Protection

Open-string protection is achieved through the OVP pin and the LED (1 to 4) pins. If one or more strings are open, the respective LEDX pins are pulled to ground. The IC continues charging the output voltage until it reaches the over-voltage protection (OVP) threshold. If the OVP point has been triggered, the chip stops switching and marks the strings that have an LEDX pin voltage lower than 206mV. Once

marked, the remaining LED strings force the output voltage back into tight regulation. The string with the largest voltage drop determines the output regulation.

The MP3385A always attempts to light at least one string. If all strings are open, the MP3385A shuts down the step-up converter. The strings remain in this marked state until the chip resets.

Unused LED String Auto-Detection

For the MP3385A, if an LED string is open or unused before start-up, the IC detects and marks off the open channel automatically to prevent the output from charging to the OVP value. This function prevents a start-up failure, which is caused by LED short string misprotection due to OVP triggering. This is useful for application use and test board debugging. The unused LED string auto-detection function is disabled if the OVP point is changed by the I²C after EN and VIN power on, and I²C is active.

The MP3385A disables the unused LED string by disabling the corresponding register control bit for each 4-channel current source. In some applications, if fewer than four LED strings are needed, the unused LED current sources can be disabled by setting the LED4:0 bit to 0 in register 00H.

Short-String Protection

The MP3385A monitors the LEDX pin voltages to determine if a short-string fault has occurred. If one or more strings are shorted, the respective LEDX pins tolerate high-voltage stress. If an LEDX pin voltage is higher than the protection threshold, which can be programmable by the LEDX2:0 bits in 01H, this condition triggers the detection of a short-string fault. When a short-string fault remains for longer than 10ms, the fault string is marked off and disabled. Once a string is marked off, it disconnects from the output voltage loop until VIN or EN restarts.

Cycle-by-Cycle Current Limit

To prevent the external components from exceeding the current stress rating, the IC uses a cycle-by-cycle current limit protection. The limit value is programmable from 150mV to

500mV by the OCP2:0 bits in register 05H. When the current exceeds the current limit value, the IC latches off until the power is reset or EN is toggled when operating in latch-off mode if the OCPM bit = 0. The device restarts when the current drops below the current limit again if the OCPM bit = 1.

Short Inductor/Diode Protection

When the external inductor or diode is shorted, the IC provides protection by detecting the current flowing through the power MOSFET. When the current sense voltage across the sense resistor (connected between IS and GND) hits the current protection threshold and lasts for four switching cycles, the IC stops switching and latches.

Thermal Shutdown Protection

To prevent the IC from operating at exceedingly high temperatures, thermal shutdown is implemented to detect the silicon die temperature. When the die temperature exceeds the upper threshold (T_{ST}), the IC shuts down. The IC resumes normal operation when the die temperature drops below the lower threshold. Typically, the hysteresis value is 25°C.

Fault Flag Output and Fault Register Indicator

FT remains in an open-drain condition when the LED driver is operating in a normal condition. It is connected to VCC by an external 100kΩ resistor and pulled to logic high when there is no fault. FT goes to logic low if a fault occurs. Set the corresponding fault bit in register 03H to 1.

I²C Interface Register Description

I²C Chip Address

After the start condition, the I²C-compatible master sends a 7-bit address followed by an eighth read (Read: 1) or write (Write: 0) bit. The bit indicates the register address to or from which the data is written or read (see Figure 3).

Bit	Bit Name	Access	Default	Description
7:0	ID7:0	R	01h	Vendor ID information. Returns 01H when read.

APPLICATION INFORMATION

Selecting the Switching Frequency

The operation frequency of the converter depends on both the resistor at OSC and the FS3:0 bit in register 01H. If a 100kΩ resistor is selected for R_{OSC} (connected to OSC), the switching frequency is set from 100kHz to 900kHz by the I²C interface. 0001b to 1001b corresponds to 100kHz to 900kHz, respectively. Table 8 shows the list of switching frequencies.

Table 8: Switching Frequencies

FS3:0	Switching Frequency	Unit
0000b	Converter off	
0001b	100	kHz
0010b	200	
0011b	300	
0100b	400	
0101b	500	
0110b	600	
0111b	700	
1000b	800	
1001b	900	

Without the I²C interface, an oscillator resistor on OSC sets the internal oscillator frequency for the step-up converter according to Equation (1):

$$F_{sw}(\text{kHz}) = \frac{40000}{R_{OSC}(\text{k}\Omega)} \quad (1)$$

When R_{OSC} = 100kΩ, then F_{SW} = 400kHz.

Setting the LED Current

The current of each LED string is set through the current setting resistor on ISET and the full scale LED current setting bits ILED7:0 in Table 3. When the INTERFACE bit in 00H is 0, the LED current is dependent on the input PWM dimming duty cycle. Calculate the setting formula using Equation (2):

$$I_{LED}(\text{mA}) = \frac{20196}{R_{ISET}(\text{k}\Omega)} * K_{FullScale} \quad (2)$$

When the INTERFACE bit in 00H is 1, calculate the setting formula using Equation (3):

$$I_{LED}(\text{mA}) = \frac{20196}{R_{ISET}(\text{k}\Omega)} * K_{DIM} * K_{FullScale} \quad (3)$$

Where K_{FullScale} is the ratio, which is set by the full scale LED current setting bits ILED7:0 in 02H, and K_{DIM} is the ratio, which is set by the dimming current setting bits DIM9:0 in 03H and 04H.

Without the I²C interface, the current of each LED string is set through the resistor on ISET according to Equation (4):

$$I_{LED}(\text{mA}) = \frac{4633}{R_{ISET}(\text{k}\Omega)} \quad (4)$$

For R_{ISET} = 46.4kΩ, the LED current is set to 100mA. Do not leave ISET open.

Selecting the Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent high-frequency switching current from passing through to the input. Ceramic capacitors with X5R or X7R dielectrics are recommended for their low ESR and small temperature coefficients. For most applications, use a 4.7μF ceramic capacitor in parallel with a 220μF electrolytic capacitor.

Selecting the Inductor and Current Sensing Resistor

A larger value inductor results in less ripple current and lower peak inductor current, which reduces stress on the N-channel MOSFET. However, the larger-value inductor has a larger physical size, a higher series resistance, and a lower saturation current. Choose an inductor that will not saturate under the worst-case load conditions. Select the minimum inductor value to ensure that the boost converter works in continuous conduction mode (CCM) with high efficiency and good EMI performance.

Calculate the required inductance value using Equation (5) and Equation (6):

$$L \geq \frac{\eta \times V_{OUT} \times D \times (1-D)^2}{2 \times f_{SW} \times I_{LOAD}} \quad (5)$$

$$D = 1 - \frac{V_{IN}}{V_{OUT}} \quad (6)$$

Where V_{IN} is the input voltage, and V_{OUT} is the output voltage, f_{SW} is the switching frequency, I_{LOAD} is the LED load current, and η is the efficiency.

Usually, the switching current is used for peak-current-mode control. To avoid reaching the current limit, the voltage across the sensing resistor (R_{SENSE}) must be less than 70% of the current-limit voltage (V_{SENSE}), in the worst cases. Calculate R_{SENSE} and $I_{L(PEAK)}$ with Equation (7) and Equation (8):

$$R_{SENSE} = \frac{0.7 \times V_{SENSE}}{I_{L(PEAK)}} \quad (7)$$

$$I_{L(PEAK)} = \frac{V_{OUT} \times I_{LOAD}}{\eta V_{IN}} + \frac{V_{IN} \times (V_{OUT} - V_{IN})}{2 \times L \times F_{SW} \times V_{OUT}} \quad (8)$$

The current limit setting voltage (V_{SENSE}) is set by the OCP2:0 bits in register 05H.

Selecting the Power MOSFET

The MP3385A is capable of driving a wide variety of N-channel power MOSFETS. The critical parameters of selection for a MOSFET are maximum drain-to-source voltage ($V_{DS(MAX)}$), maximum current ($I_{D(MAX)}$), on resistance ($R_{DS(ON)}$), gate-source charge (Q_{GS}) and gate-drain charge (Q_{GD}), and total gate charge (Q_G).

Ideally, the off-state voltage across the MOSFET is equal to the output voltage. Considering the voltage spike when it turns off, $V_{DS(MAX)}$ should be greater than 1.5 times the output voltage.

The maximum current through the power MOSFET occurs at the minimum input voltage and the maximum output power. The maximum RMS current through the MOSFET is given by Equation (9) and Equation (10):

$$I_{RMS(MAX)} = I_{IN(MAX)} \times \sqrt{D_{MAX}} \quad (9)$$

$$D_{MAX} \approx \frac{V_{OUT} - V_{IN(MIN)}}{V_{OUT}} \quad (10)$$

The current rating of the MOSFET should be greater than 1.5 times I_{RMS} .

The on resistance of the MOSFET determines the conduction loss, which can be calculated with Equation (11):

$$P_{COND} = I_{RMS}^2 \times R_{DS(on)} \times k \quad (11)$$

Where k is the temperature coefficient of the MOSFET.

The switching loss is related to Q_{GD} and Q_{GS} , which determine the commutation time. Q_{GS1} is the charge between the threshold voltage and the plateau voltage when a driver charges the gate, which can be read in the V_{GS} vs. Q_G chart in the MOSFET datasheet. Q_{GD} is the charge during the plateau voltage. These two parameters are needed to estimate turn-on and turn-off losses and can be calculated with Equation (12):

$$P_{SW} = \frac{Q_{GS1} \times R_G}{V_{DR} - V_{TH}} \times V_{DS} \times I_{IN} \times f_{SW} + \frac{Q_{GD} \times R_G}{V_{DR} - V_{PLT}} \times V_{DS} \times I_{IN} \times f_{SW} \quad (12)$$

Where V_{TH} is the threshold voltage, V_{PLT} is the plateau voltage, R_G is the gate resistance, and V_{DS} is the drain-source voltage.

Please note that calculating the switching loss is the most difficult part of loss estimation. The formula above provides a simplified equation. For more accurate estimates, the equation becomes much more complex. The total gate charge (Q_G) is used to calculate the gate-drive loss, shown in Equation (13):

$$P_{DR} = Q_G \times V_{DR} \times f_{SW} \quad (13)$$

Where V_{DR} is the drive voltage.

Selecting the Output Capacitor

The output capacitor keeps the output voltage ripple small and ensures feedback loop stability. The output capacitor impedance must be low at the switching frequency. Ceramic capacitors with X7R dielectrics are recommended for their low ESR characteristics. For most applications, a 4.7 μ F ceramic capacitor in parallel with a 22 μ F electrolytic capacitor is sufficient.

Setting the Over-Voltage Protection (OVP)

Open-string protection is achieved through the detection of the voltage on the OVP pin. In some cases, an LED string failure results in the feedback voltage always being zero. The MP3385A continues boosting the output voltage higher and higher. If the output voltage reaches the programmed OVP threshold, the protection is triggered.

To ensure that the chip functions properly, an appropriate OVP voltage is needed. The recommended OVP point is about 1.1 to 1.2 times higher than the output voltage for normal operation. If the OVP pin is connected to the anode of the LED load, the OVP voltage is set by the OVP4:0 bits in register 05H. It is not recommended to set the OVP value higher than 80V, considering the LED return pin voltage rating.

If the MP3385A is applied for >80V output voltage applications through an external extension, connect a proper resistor (R_{OVP}) between the anode of the LED and OVP pins to change the over-voltage point of the output (V_{OVP}). Calculate V_{OVP} with R_{OVP} with Equation (14):

$$V_{OVP}(V) = \frac{R_{OVP}(k\Omega) + 1600}{40} * 1.9 \quad (14)$$

Where the OVP4:0 bit in register 05H is the set default.

Expanding LED Channels

The MP3385A expands the number of LED channels by using two or three ICs in parallel. To connect two ICs for a total of eight LED strings, tie the VCC pins of the master IC and the slave IC together to power the slave IC internal logic circuitry. Tie the COMP pins of the slave IC and the master IC together to regulate the voltage of all eight strings. The slave IC MOSFET driving signals are not used. The boost converter can be driven only by the master IC. Do not leave IS of the slave IC floating; tie it to ground. Apply the EN and DIM signals to both ICs. The master IC's OVP should be higher than the slave IC's OVP.

PCB Layout Guidelines

Efficient PCB layout is critical to reduce EMI noise and achieve stable operation. For best results, refer to the guidelines below.

1. Keep the loop from the external MOSFET through the output diode and the output capacitor as small and short as possible since they carry a high-frequency pulse current.
2. Separate the power ground (PGND) and signal ground (GND).
3. Connect PGND and GND together. All logic signals refer to the signal ground to reduce noise affection.
4. Place the ceramic capacitors for VIN and VCC as close as possible.

TYPICAL APPLICATION CIRCUIT

Figure 4: Driving 4 LED Strings

NOTE: Remove the LPF capacitor (C5) when the MP3385A works in direct PWM dimming.
Some components value may need to be adjusted for different application condition.
