**DESCRIPTION**

The MP44014 is a boundary conduction mode PFC controller that provides simple, high-performance, active power factor correction using minimal external components.

The output voltage is regulated accurately by a high-performance voltage mode amplifier with an accurate internal voltage reference.

The precise, adjustable output over-voltage protection greatly enhances system reliability.

The on-chip R/C filter on the current sense pin can potentially eliminate the external R/C filter.

The extremely low start-up current, quiescent current, and disable function reduces power consumption, resulting in excellent efficiency performance.

The MP44014 is available in a SOIC-8 package.

**FEATURES**

- Boundary Conduction Mode PFC Controller for Pre-Regulator
- Zero-Crossing Compensation to Minimum THD of the AC Input Current
- Precise Adjustable Output Over-Voltage Protection
- Ultra-Low (15μA) Start-Up Current
- Low Quiescent Current (0.46μA) at OVP Condition
- On-Chip Filter on Current Sense Pin
- Disable Function on ZCS Pin
- -750mA/+800mA Peak Gate Drive Current
- Available in SOIC-8 Packages

**APPLICATIONS**

- Offline Adaptors
- Electronic Ballast
- LLC Front End
- Other PFC Pre-Regulators

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance.

MP44014: Part number
LLLLLLLL: Lot number
MPS: MPS prefix
Y: Year code
WW: Week code

PACKAGE REFERENCE

ABSOLUTE MAXIMUM RATINGS (1)
Supply voltage (VCC) .............. -0.5V to self limit
Analog inputs and outputs (2)...........-0.3V to 6.5V
ZCS max. current .....................-2.5mA to 10mA
Continuous power dissipation (T_A = +25°C) (3)
SOIC-8 ............................................. 1.4W
Junction temperature ................... –40°C to +125°C
Lead temperature (solder) ............... 260°C
Storage temperature .................. -55°C to +150°C

Recommended Operating Conditions (4)
Supply voltage (VCC) .............. 13.4V to 22V
Analog inputs and outputs .......... -0.3V to 6.5V
Operating junction temp. (T_J) .... -40°C to +125°C

Thermal Resistance (5)
SOIC-8 ............................................. 90 ........................ 45 ...°C/W

NOTES:
1) Exceeding these ratings may damage the device.
2) Except ZCS pin, which is self limited.
3) The maximum allowable power dissipation is a function of the
   maximum junction temperature T_J(MAX), the junction-to-
   ambient thermal resistance θ_JA, and the ambient temperature
   T_A. The maximum allowable continuous power dissipation at
   any ambient temperature is calculated by
   D(MAX)=(T_J(MAX)-T_A)/θ_JA. Exceeding the maximum
   allowable power dissipation will produce an excessive die
   temperature, causing the regulator to go into thermal
   shutdown. Internal thermal shutdown circuitry protects the
   device from permanent damage.
4) The device is not guaranteed to function outside of its
   operating conditions.
5) Measured on JESD51-7, 4-layer PCB.
## ELECTRICAL CHARACTERISTICS

$V_{CC} = 15V$, $C_{GATE} = 1\, \text{nF}$, $T_J = -40^\circ\text{C}--+125^\circ\text{C}$, unless otherwise noted.

FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram
OPERATION

The MP44014 is a boundary conduction mode PFC controller optimized for the PFC pre-regulator up to 300W and fully complies with IEC1000-3-2 specification.

Output Voltage Regulation

The output voltage is sensed at FB through a resistor divider from the output voltage to ground. The accurate on-chip reference voltage and the high performance error amplifier regulate the output voltage accurately.

Over-Voltage Protection (OVP)

The MP44014 offers two stages of over-voltage protection: dynamic over-voltage protection and static over-voltage protection. With two-stage protection, the circuit operates reliably.

The MP44014 achieves OVP by monitoring the current flow through COMP.

During steady-state operation, the current flow through the high-side feedback resistor (R9) and the low-side feedback resistor (R10) is calculated with Equation (1):

$$ I_{R9} = \frac{V_D - V_{FB}}{R9} = I_{R10} = \frac{V_{FB}}{R10} $$

(1)

If there is an abrupt rise on the output ($\Delta V_O$) and the compensation network connected between FB and COMP takes time to achieve high power factor (PF) due to the long RC time constant, the voltage on FB will still be kept at the reference value. The current through R10 remains equal to $V_{FB}/R10$. However, the current through R9 is calculated with Equation (2):

$$ I'_{R9} = \frac{V_D + \Delta V_O - V_{FB}}{R9} $$

(2)

This current has to flow into COMP. Simultaneously, this current is monitored inside the chip. If the current rises to 35µA, the output voltage of the multiplier will be forced to decrease, and the energy delivered to the output will be reduced. If this current continues to rise to about 40µA, the dynamic OVP can be triggered. Consequently, the gate driver is blocked to turn off the external power MOSFET, and the device enters an idle state. This state is maintained until the current falls below 10µA, the point at which the internal starter will be re-enabled and allow the switching to restart.

When the load is very light, the output voltage tends to stay steadily above the nominal value. In this condition, the error amplifier output will saturate low. When the error amplifier output is lower than 2.25V, static OVP will be triggered. Consequently, the gate driver will be blocked to turn off the external power MOSFET, and the device will enter an idle state. Normal operation resumes once the error amplifier output returns to the regulated region (see Figure 2).

Disable Function

The MP44014 can be disabled by pulling the zero-current sensing (ZCS) pin lower than 190mV. This helps to further reduce quiescent current when the PFC pre-regulator needs to be shut down. After releasing ZCS, it will stay at a lower clamp voltage when there is no external voltage from the auxiliary winding (see Figure 3).
Boundary Conduction Mode
When the current of the boost inductor reaches zero, the voltage on the inductor is reversed. ZCS then generates the turn-on signal of the MOSFET by sensing the falling edge of the voltage on the auxiliary winding coupled with the inductor. If the ZCS voltage rises above 2.1V, the comparator waits until the voltage falls below 1.6V. Once the voltage falls below 1.6V, the MP44014 turns on the MOSFET. The 7.8V high clamp and 0.55V low clamp protect ZCS. The internal 175µs timer generates a signal to turn on the MOSFET if the driver signal has been low for more than 175µs. This also allows the MOSFET to turn on during the start-up period since no signal is generated from ZCD during start-up.

Zero-Crossing Compensation
The MP44014 offers 30mV voltage offset for the multiplier output near the zero crossing of the line voltage (which can force the circuit to process more energy at the bottom of the line voltage). With this function, the THD of the current is reduced.

To prevent redundant energy, this offset is reduced as the instantaneous line voltage increases. Therefore the offset will be negligible near the top of the line voltage.

Power Factor Correction
The MP44014 senses the inductor current through the current sense pin and compares it to the sinusoidal-shaped signal, which is generated from the output of the multiplier. When the external power MOSFET turns on, the inductor current rises linearly. When the peak current hits the sinusoidal-shaped signal, the external power MOSFET begins to turn off, and the diode turns on. Also, the inductor current begins to fall. When the inductor current reaches zero, the power MOSFET begins to turn on again, which causes the inductor current to start rising again. The power circuit works in boundary conduction mode, and the envelope of the inductor current is sinusoidal shaped. The average input current is half of the peak current, so the average input current is also sinusoidal shaped. A high power factor can be achieved through this control method (see Figure 4).

Power Factor Correction
The MP44014 senses the inductor current through the current sense pin and compares it to the sinusoidal-shaped signal, which is generated from the output of the multiplier. When the external power MOSFET turns on, the inductor current rises linearly. When the peak current hits the sinusoidal-shaped signal, the external power MOSFET begins to turn off, and the diode turns on. Also, the inductor current begins to fall. When the inductor current reaches zero, the power MOSFET begins to turn on again, which causes the inductor current to start rising again. The power circuit works in boundary conduction mode, and the envelope of the inductor current is sinusoidal shaped. The average input current is half of the peak current, so the average input current is also sinusoidal shaped. A high power factor can be achieved through this control method (see Figure 4).

Zero-Crossing Compensation
The MP44014 offers 30mV voltage offset for the multiplier output near the zero crossing of the line voltage (which can force the circuit to process more energy at the bottom of the line voltage). With this function, the THD of the current is reduced.

To prevent redundant energy, this offset is reduced as the instantaneous line voltage increases. Therefore the offset will be negligible near the top of the line voltage.

Power Factor Correction
The MP44014 senses the inductor current through the current sense pin and compares it to the sinusoidal-shaped signal, which is generated from the output of the multiplier. When the external power MOSFET turns on, the inductor current rises linearly. When the peak current hits the sinusoidal-shaped signal, the external power MOSFET begins to turn off, and the diode turns on. Also, the inductor current begins to fall. When the inductor current reaches zero, the power MOSFET begins to turn on again, which causes the inductor current to start rising again. The power circuit works in boundary conduction mode, and the envelope of the inductor current is sinusoidal shaped. The average input current is half of the peak current, so the average input current is also sinusoidal shaped. A high power factor can be achieved through this control method (see Figure 4).
