**DESCRIPTION**

The MP4700 is a high-efficiency step-down converter designed to drive high-brightness light emitting diodes.

The MP4700 drives an external MOSFET in boundary conduction mode, which features no reverse recovery loss in the freewheeling diode and soft turn-on with zero-current and valley voltage for the power MOSFET that improves efficiency and minimizes the inductor value and size. The boundary conduction control mode regulates the LED current by sensing the MOSFET peak current through an external resistor. Its low 300mV feedback voltage reduces power loss and improves efficiency.

The MP4700 implements PWM dimming to the LED current.

Protection features include output short protection, under-voltage lockout for the IC input voltage and bus input voltage, a limited maximum switching frequency, and thermal shut down.

**FEATURES**

- 8V-to-18V Input Voltage
- Constant-Current LED Driver
- Power MOSFET Zero-Current Turn-On
- No Freewheeling Diode Reverse Recovery Issues
- High Efficiency and Reliability in Boundary Conduction Mode
- Low 1mA Operation Current
- PWM Dimming Control
- Hiccup Short Circuit Protection
- UVLO for Bus Input Voltage
- Input UVLO, Thermal Shutdown
- Maximum Frequency Limited to 160kHz
- Available in SOIC8 Package

**APPLICATIONS**

- LED Backlighting for TV and Monitor
- DC/DC or AC/DC LED Driver applications
- General Illumination
- Industrial Lighting
- Automotive/Decorative LED Lighting

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are Registered Trademarks of Monolithic Power Systems, Inc.

Notes:
1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature \(T_J\) (MAX), the junction-to-ambient thermal resistance \(\theta_{JA}\), and the ambient temperature \(T_A\). The maximum allowable continuous power dissipation at any ambient temperature is calculated by \(P_D (\text{MAX}) = \frac{(T_J(\text{MAX}) - T_A)\theta_{JA}}{\theta_{JA}}\). Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.

FUNCTIONAL BLOCK DIAGRAM

![Block Diagram](image)

Figure 1: Block Diagram
OPERATION

Internal Regulator
The MP4700 uses a low dropout (LDO) regulator to supply the IC. Use a DC voltage in the range of 8V to 18V to power the IC.

The internal LDO regulator maintains the VCC voltage at 8.4V when the input voltage is less than 12V. The VCC pin requires a ceramic bypass capacitor.

When the input voltage exceeds 12V, the LDO regulator switches to switch-controlled current source mode. The VCC voltage charges to its peak voltage (9.8V) and then the current source stops. After the VCC voltage decreases to its valley voltage (9V), the current source turns on again. This switch-controlled current source mode reduces the LDO power consumption and improves efficiency.

LED Current Regulation and Valley Detection
In floating-buck-converter configuration, as shown in the typical application circuit, the MP4700 controls the MOSFET (Q1) using peak current control. The CS pin senses the peak current through a resistor ($R_{\text{sense}}$) to regulate the current to:

$$I_{\text{PEAK}} = \frac{302mV}{R_{\text{sense}}}$$

In normal operation, the MP4700 turns on Q1 when the current in the freewheeling diode goes to zero. As a result, the average LED current is:

$$I_{\text{LED}} = \frac{302mV}{2R_{\text{sense}}}$$

The zero-current detection is realized at the DRV pin by sensing the MOSFET drain $dv/dt$ current through the Q1’s miller capacitor. When the current through the freewheeling diode goes to zero, the Q1 drain voltage ($V_{SW}$) drops from $V_{\text{Bus}}$ to $(V_{\text{Bus}} - V_{\text{OUT}})$ and oscillates thanks to the inductor and the parasitic capacitors. When $V_{SW}$ drops to the minimum value, the $dv/dt$ current through the miller capacitor rises from negative to zero. At this point, the MP4700 turns on Q1 as the inductor current goes to zero and the Q1 drain voltage is at its minimum.

The MP4700 controls the buck converter in current-boundary-conduction mode.

To improve zero current detection, add a 10pF capacitor between the Q1 drain and source.

Add a capacitor ($C_{\text{out}}$) in parallel to the LED string to reduce the current ripple.

Boundary operation mode minimizes the Q1 turn-on loss and eliminates the freewheeling diode’s reverse recovery loss to reduce passive components’ size requirements at high switching frequencies. Furthermore, the required inductance value is already small, further reducing the inductor size.

Brightness Dimming Control
The MP4700 employs PWM dimming to control the LED current. Use a 100Hz-to-2kHz PWM signal. PWM input high triggers IC switching. PWM input low turns off the IC.

For applications that do not need PWM dimming control, apply a high voltage on the PWM pin or leave the PWM pin open.

Frequency Setting and Inductor Design
In case the zero-current detection circuit fails—which can happen at start-up during an output short condition with a large output capacitor—applying a maximum off time of about 2.8ms ensures that the MP4700 continues to operate and the prevents short current runaway.

The MP4700 has a maximum switching frequency of 160kHz to avoid extreme circuit losses and ensure better EMI performance. If the converter reaches the maximum frequency, it will operate in discontinuous current conduction mode. Avoid this operation mode since the LED current is out of regulation.

Inductor design is critical to ensure that the switching frequency ($f_s$) is within the 30kHz to 160kHz range.

$$L = \frac{1}{f_s \cdot 2 \cdot I_{\text{LED}} \cdot (V_{\text{Bus}} - V_{\text{OUT}})} \cdot \frac{V_{\text{OUT}}}{V_{\text{Bus}}}$$

Where $V_{\text{Bus}}$ is the input voltage of the Buck converter, and $V_{\text{OUT}}$ is the LED voltage.
Hiccup Output-Short Protection

If the entire LED string is shorted, $V_{OUT}$ is zero. Due to the minimal on time limit, the inductor current will be out of regulation. The MP4700 can detect this failure and shut down for about 2.8ms, and then re-tries the operation. This hiccups protection can eliminate thermal issues due to a short-circuit current, and also maintain normal operation if the protection is mis-triggered.

Input-Bus-Voltage Under-Voltage Lockout (UVLO) Protection

The MP4700 implements UVLO protection for the input bus voltage. The INUV pin senses the input bus voltage through a voltage divider. The IC is locked out until the input bus voltage rises so that the INUV voltage pin exceeds its UVLO threshold. This UVLO function protects against a low input bus voltage. For best results, set the input bus voltage UVLO point over 1.1 times the output LED voltage.

Set the input bus UVLO as follows:

$$\frac{R_{\text{INU}}}{R_{\text{INU_L}}} = \frac{V_{\text{Bus-UVLO}}}{V_{\text{INU_TH}}}$$

Where $V_{\text{INU_TH}}=1.2V$ is the INUV pin threshold voltage.

VCC Under-Voltage Lockout (UVLO) Protection

Under-voltage lockout (UVLO) protects the chip from operating at an insufficient supply voltage. The UVLO rising threshold is about 7.4V while its falling threshold is a consistent 6.4V.

Thermal Shutdown Protection

An accurate temperature protection prevents the chip from operating at exceedingly high temperatures. When the silicon die temperature exceeds its upper threshold, it shuts down the whole chip. When the temperature drops below its lower threshold, the chip is enabled again.
**DESIGN EXAMPLE**

**TV LED Backlighting**

The design example introduces an MP4700-based high-performance TV LED backlighting solution. Figure 2 shows the structure of this total system solution—Flyback+MP4700 low-side buck for single-string TV LED backlight. The flyback converts the AC input line voltage to the system output supply voltage 13V/2A, and also outputs a DC bus voltage (around 280V) to the LED driver. The flyback is based on the MPS quasi-resonant flyback controller, HFC0100. The MP4700 acts as the LED driver stage as a boundary conduction mode (BCM) low-side buck.

Protection: short LED protection, open LED protection and 13V over-voltage protection.

**Schematics:**

Figure 3 and Figure 4 show the schematics of the HFC0100 flyback stage and the MP4700 LED driver stage. The parameters of the power transformer T2 are as follow:

Turn ratio:

\[ N_p : N_{bus1} : N_{bus2} : N_{13V} : N_Au = 45:51:51:5:10 \]

Primary inductance: \( L_p \approx 360 \mu H \).

In this application example, the bus voltage uses 2 windings. Each winding outputs half of the bus voltage (140V) after the rectifier, dividing the voltage stress across each rectifier diode. The reduced stress allows for the use of 800V diodes.

Both the 13V voltage and the 280V bus voltage feed back to the flyback control circuit, which decreases the influence of the cross regulation.

The 13V system voltage also supplies the MP4700.

The following describes the design of the MP4700 LED driver. The design procedure for the HFC0100 flyback is not described here, but rather in the HFC0100 design materials.
Figure 3: HFC0100 Flyback Schematic

Figure 4: MP4700 Low-Side Buck LED Driver Schematic
Select the Inductor

The MP4700 operates at BCM. Select a proper inductor to ensure that the operating frequency is within a desired range.

Assuming the 280V bus voltage has -10% to +20% variation, and the LED voltage has a ±10% variation. The maximum system operating frequency at the maximum input bus voltage and the minimum output LED voltage should not exceed the MP4700’s 160kHz frequency limit.

\[ L \geq \frac{1}{f_{s,\text{max}} \cdot 2 \cdot I_{\text{LED}}} \frac{(V_{\text{Bus, max}} - V_{\text{LED, min}}) \cdot V_{\text{LED, min}}}{V_{\text{bus, max}}} \]

Choosing a maximum operating frequency at 150kHz, the inductor should exceed 1.1mH. The peak inductor current is around 2 times the LED current when the MP4700 operates in BCM. An inductor rated at 1.3mH/0.6A would fit this application.

Select the Power MOSFET

The voltage stress of the power MOSFET should exceed the bus voltage. A MOSFET with 400V voltage rating will suffice for this application. The peak current through the MOSFET equals the peak inductor current, or 2 times the LED current (250mA). The maximum RMS current through the MOSFET is:

\[ I_{\text{RMS, MOS, max}} = 2I_{\text{LED}} \frac{V_{\text{LED, max}}}{\sqrt{3V_{\text{bus, min}}}} = 0.27A \]

Choose a MOSFET with a current rating around 2A to 3A.

Select the Diode

The voltage stress of the diode should exceed the bus voltage—400V will suffice for this application. The maximum average current through the diode is:

\[ I_{\text{Avg, Diode, max}} = 2I_{\text{LED}} \left(1 - \frac{V_{\text{LED, min}}}{V_{\text{bus, max}}} \right) = 0.21A \]

This allows for a current rating within 1A to 2A.

Select the Current Sense Resistor

The MP4700 operates in BCM and the current sense resistor is:

\[ R_{\text{sense}} = \frac{302mV}{2 \cdot I_{\text{LED}}} = 600\Omega \]

Select the Output Capacitor

The output capacitor should be large enough to filter the output ripple current and limit the LED current ripple to within a desired range (usually below ±5%).

Use the equivalent dynamic resistance of the LED string to design the output capacitor. Figure 5 defines the equivalent dynamic resistance of the LED string (R_{L,\text{LED}}).

\[ R_{L,\text{LED}} = \frac{\Delta V_{\text{LED}}}{\Delta I_{\text{LED}}} \]

Figure 5: LED Equivalent Dynamic Resistance

Calculate the value of the ceramic output capacitor as:

\[ C_{\text{OUT}} \geq \frac{I_{\text{PEAK}}}{8f_{s,\text{min}} \cdot R_{L,\text{LED}} \cdot I_{\text{LED, ripple, pk, pk}}} \]

Where \( f_{s,\text{min}} \) is the minimum operating frequency, which occurs at the minimum input voltage and maximum output voltage condition for this application.
Considering that $I_{L\_PEAK}=2\times I_{LED}$, the output capacitor value is:

$$C_{OUT} \geq \frac{L \cdot I_{LED}^2 \cdot V_{bus\_min} \cdot V_{LED\_max} \cdot R_{LED} \cdot I_{LED\_ripple\_pk\_pk}}{2(V_{bus\_min} - V_{LED\_max}) \cdot V_{LED\_max} \cdot V_{L\_PEAK \cdot bus\_min}}$$

If using an electrolytic output capacitor, its ESR dominates its impedance. The ESR value should be:

$$R_{ESR\_COUT} < \frac{R_{LED} \cdot I_{LED\_ripple\_pk\_pk}}{I_{L\_PEAK}}$$

Usually, a 1μF to 2.2μF ceramic capacitor or a 10μF to 22μF electrolytic capacitor should suffice for this LED current level.

**Select the Input Capacitor**

Select the input capacitor to ensure that the input voltage ripple is within a desired range (1% to 5% of the input bus voltage). The input capacitor is usually electrolytic and its ESR dominates its impedance. The ESR of this input capacitor should be:

$$R_{ESR\_Cin} < \frac{V_{bus\_ripple\_PK\_PK}}{I_{L\_PEAK}}$$

A 4.7μF to 22μF electrolytic capacitor will usually suffice.

**PCB Layout Guide**

For best results, follow these layout guidelines for the MP4700 low-side buck:

1. Make the high-frequency switching loop (the input capacitor, the diode, the power MOSFET and the current sense resistor) as small and tight as possible.

2. Place the current sense resistor close to the IC and make the current sense loop as small as possible.

3. Separate the GND of MP4700 from the power ground of system, which conducts current of power stage.

Figure 6 and Figure 7 show an example of the PCB layout. Figure 7 shows the high-frequency switching loop (composed of the input capacitor, the diode, the power MOSFET and the current sense resistor) marked in red. Make sure to minimize this high-frequency switching loop.
