DESCRIPTION
The MP6906 is a low-drop diode emulator IC that combines an external switch to replace Schottky diodes in high-efficiency flyback converters. The chip regulates the forward drop of an external switch to about 30mV and switches it off as soon as the voltage becomes negative.

The MP6906 provides a SYNC interface to receive an external signal to shut down the gate driver for reliable continuous conduction mode (CCM) operation. A programmable light-load sleep mode reduces the IC’s quiescent current to 150µA. Also, it has a low UVLO level for operation at a lower output without an additional winding. Rail-to-rail output provides higher driving voltage to the external MOSFET.

The MP6906 is available in compact SOIC-8 and TSOT23-6 packages.

FEATURES
• Works with 12V Standard and 5V Logic Level FETS
• Fast Turn-Off Total Delay of 25ns
• 4.2V~35V Wide VDD Operating Range
• 30mV V_DS Regulation Function (1)
• 150µA Quiescent Current in Light-Load Mode (1)
• Supports DCM and Quasi-Resonant Operation
• SYNC Interface for CCM Operation
• Supports High-side and Low-side Rectification
• Power Savings of up to 1.5W in a Typical Notebook Adapter
• SOIC-8 and TSOT23-6 Packages

APPLICATIONS
• Industrial Power Systems
• Distributed Power Systems
• Battery Powered Systems
• Flyback Converters

NOTE:
1) Related issued patent: US Patent US8,067,973; US8,400,790. CN Patent ZL201010504140.4; ZL200910059751.X. Other patents pending.

TYPICAL APPLICATION

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance.

ABSOLUTE MAXIMUM RATINGS (2)
V_{DD} to V_{SS} .................. –0.3V to +38V
PGND to V_{SS} .................. –0.3V to +0.3V
V_{G} to V_{SS} .................. –0.3V to +20V
V_{D} to V_{SS} .................. –1V to +180V
SYNC, LL, EN to V_{SS} .......... –0.3V to +6.5V
Continuous power dissipation (T_{A} = +25°C) (3)
SOIC-8 ........................................................ 1.4W
TSOT23-6 ................................................. 0.57W
Junction temperature .................. 150°C
Lead temperature (solder) ........... 260°C
Storage temperature ..............–55°C to +150°C

Recommended Operation Conditions (4)
V_{DD} to V_{SS} .................. 4.2V to 35V
Operating junction temp. (T_{J}) .... -40°C to +125°C

Thermal Resistance (5) \( \theta_{JA} \quad \theta_{JC} \)
SOIC-8 ........................................... 90 .... 45 ... °C/W
TSOT23-6 .......................... 220 .... 110 .. °C/W

NOTES:
2) Exceeding these ratings may damage the device.
3) The maximum allowable power dissipation is a function of the maximum junction temperature T_{J(MAX)}, the junction-to-ambient thermal resistance \( \theta_{JA} \), and the ambient temperature T_{A}. The maximum allowable continuous power dissipation at any ambient temperature is calculated by \( P_{D(MAX)}=(T_{J(MAX)}-T_{A})/\theta_{JA} \). Exceeding the maximum allowable power dissipation will produce an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
4) The device is not guaranteed to function outside of its operating conditions.
5) Measured on JESD51-7, 4-layer PCB.

FUNCTIONAL BLOCK DIAGRAM

Figure 1: MP6906 Block Diagram
OPERATION

The MP6906 supports operation in DCM and quasi-resonant flyback converters. The control circuitry controls the gate in forward mode and turns the gate off when the MOSFET current is fairly low.

VD Clamp
Because V_D can go as high as 180V, a high-voltage JFET is used at the input. To avoid excessive currents when V_g drops below -0.7V, a 1kΩ resistor is recommended between V_D and the drain of the external MOSFET.

Under-Voltage Lockout (UVLO)
When V_DD is below the 4.2V UVLO threshold, the part enters sleep mode, and V_G remains at a low level.

Enable (EN)
If EN is pulled low, the part is in shutdown mode, which consumes <150μA shutdown current. If EN is pulled high during the rectification cycle, the gate driver will not start until the next rectification cycle starts (see Figure 2).

Thermal Shutdown
If the junction temperature of the chip exceeds 150°C, V_g is pulled low, and the part stops switching. The part returns to normal operation after the junction temperature has dropped to 120°C.

Turn-On Phase
When the switch current flows through the body diode of the MOSFET, there is a negative V_{DS} (V_D-V_{SS}) across it (<-500mV). The V_{DS} is much lower than the forward voltage drop of the control circuitry (-30mV), which turns on the MOSFET after a turn-on delay (see Figure 3).

Turn-On Blanking
The control circuitry contains a blanking function. When the MOSFET turns on, the control circuitry ensures the on state lasts for a specific period of time. The turn-on blanking time is ~1.6μs, during which the turn-off threshold is blanked (see Figure 3).

Conduction Phase
When V_{DS} rises above the forward voltage drop (-30mV), according to the decrease of the switching current, the MP6906 pulls down the gate voltage level to make the on resistance of the synchronous MOSFET larger to ease the rise of Vds.

With this control scheme, V_{DS} is adjusted to around -30mV, even when the current through the MOSFET is fairly low. This function keeps the driver voltage at a very low level when the synchronous MOSFET is about to be turned off, which boosts the turn-off speed.

Turn-Off Phase
When V_{DS} rises to trigger the turn-off threshold (0mV), the gate voltage is pulled to zero after a very short turn-off delay (see Figure 3).

Turn-Off Blanking
After the gate driver is pulled to zero by V_{DS} reaching the turn-off threshold (0mV), a turn-off blanking time is applied, during which the gate driver signal is latched off. The turn-off blanking is removed when the V_{DS} voltage rises above 2V (see Figure 3).
SYNC Turn-Off for CCM Operation

An external turn-off signal can be applied on SYNC to turn-off the gate driver signal, which provides more reliable operation in CCM.

A rising edge, exceeding 2V, applied on SYNC turns off the gate driver signal immediately (see Figure 4).

The gate driver of the MP6906 will remain low as long as the SYNC voltage is high.

![Figure 4: SYNC Turn Off for CCM](image)

Light-LoadLatch-Off Function

The gate driver of the MP6906 is latched off to save driver loss and improve efficiency during a light-load condition.

When the synchronous MOSFET conducting period remains lower than \( T_{LL} \), for longer than the light-load-enter delay \( (T_{LL-Delay}) \), the MP6906 enters light-load mode and latches off the gate driver (see Figure 5). The synchronous MOSFET conducting period lasts from the time the gate driver turns on until \( V_{GS} \) drops below 1V (\( V_{LL-GS} \)).

![Figure 5: MP6906 Enters Light-Load Mode](image)

During light-load mode, the MP6906 monitors the synchronous MOSFET body diode conducting period by sensing the time duration of when \( V_{DS} \) is below -250mV (\( V_{LL-DS} \)). If the time duration is longer than \( T_{LL}+T_{LL-H} \) (\( T_{LL-H} \) is the light-load-enter pulse width hysteresis), the light-load mode ends, and the gate driver is unlatched to re-start the synchronous rectification (see Figure 6).

![Figure 6: MP6906 Exits Light-Load Mode](image)

The MP6906 enters light-load mode when the SYNC voltage is pulled high (>2V) for more than 100µs. The light-load mode ends once the SYNC voltage is pulled low (see Figure 7).

![Figure 7: Light-Load Mode Controlled by SYNC](image)
If the light-load mode ends during the rectification cycle, the gate driver signal will not show up until the next rectification cycle starts (see Figure 8).

![Figure 8: Gate Driver Start after Existing Light-Load Mode](image)

**Typical System Implementations**

Figure 9 shows the typical system implementation for the IC power supply directly derived from the output voltage, which is available in low-side rectification. The IC benefits from the wide $V_{DD}$ operating range (4.2V to 35V). The MP6906 supports most application fields with low-side rectification by directly deriving the supply power from the system output.

If the output voltage is out of the $V_{DD}$ operating range or high-side rectification is used, an auxiliary winding solution for the IC’s power supply is recommended (see Figure 10 and Figure 11). The auxiliary winding turn count ($N_{aux}$) can be set using Equation (2):

$$N_{aux} = \frac{V_{DD}}{V_{OUT}} \cdot N_s$$

(2)

Where $N_s$ is the secondary winding turn count.

![Figure 10: IC Power Derived from the Auxiliary Winding in Low-Side Rectification](image)

![Figure 11: IC Power Derived from the Auxiliary Winding in High-Side Rectification](image)

A simple non-auxiliary-winding solution for the IC’s power supply is provided in Figure 12 and Figure 13. The IC power is derived from the secondary transformer winding through a diode. When using this power solution, make sure the winding voltage is lower than the higher limit of the $V_{DD}$ operating range (35V). The winding voltage is $V_S = V_{OUT} + V_{IN_{MAX}}/n$ in Figure 12 where $V_{OUT}$ is the output voltage, $V_{IN_{MAX}}$ is the maximum input voltage, and $n$ is the transformer turn ratio. $V_S = V_{IN_{MAX}}/n$ in Figure 13.

![Figure 12: IC Power Derived from the Secondary Winding in Low-Side Rectification](image)
If the secondary winding voltage exceeds the higher limit of the $V_{DD}$ operating range (35V), an external LDO circuit with a Zener diode is needed for the non-auxiliary-winding solution (see Figure 14 and Figure 15).

To achieve fairly high use of the MOSFET’s $R_{DS(ON)}$, the MOSFET should be turned on completely for at least 50% of the SR conduction period. See Equation (3):

$$V_{ds} = -I_c \times R_{on} = -2 \cdot I_{OUT} \times R_{on} \leq V_{fwd}$$  (3)

Where $V_{DS}$ is the drain-source voltage of the MOSFET, and $V_{fwd}$ is the forward voltage threshold (~30mV).

The MOSFET’s $R_{DS(ON)}$ is recommended no lower than $\sim 15/I_{OUT}$ (mΩ). (For example, for a 5A application, the $R_{DS(ON)}$ of the MOSFET is recommended no lower than 3mΩ.)

Efficient PCB layout is critical for optimal operation. For best results, refer to Figure 17, Figure 18, and Figure 19 and follow the guidelines below:

1. Make the sensing connection (VD/VSS) as close as possible to the MOSFET (drain/source).
2. Make the sensing loop as small as possible and place the VD resistor close to VD.
3. Keep the IC out of the power loop to make sure the sensing loop and power loop do not interrupt each other (see Figure 17).
Figure 17: Voltage Sensing for \( V_D/V_{SS} \) on MP690

4. Place a decoupling ceramic capacitor (no smaller than 1\( \mu \)F) from VDD to PGND close to the IC to get adequate filtering.

Gate Driver Loop

1. Make the gate driver loop as small as possible in order to minimize the parasitic inductance.

2. Keep the driver signal far away from the VD sensing trace on the layout.

Layout Example

Figure 18 shows a layout example of a single layer with a through-hole transformer and a TO220 package SR FET. \( R_{SN} \) and \( C_{SN} \) are the RC snubber network for the SR FET.

The sensing loop (VD and VSS to the SR FET) is minimized and kept separate from the power loop. The VDD decoupling capacitor (C4) is placed beside VDD.

Figure 19 shows another layout example of a single layer with a PowerPAK/SO8 package SR FET, which also has a minimized sensing loop and power loop to avoid the loops interfering with one another.
