**DESCRIPTION**

The MP6908L is a low-drop diode emulator IC. When combined with an external switch, the MP6908L can replace Schottky diodes in high-efficiency flyback converters. The MP6908L regulates the forward drop of an external synchronous rectifier (SR) MOSFET to about 40mV, then switches off once the voltage becomes negative.

The MP6908L can generate its own supply voltage for battery charging applications that can have low output voltage or short-circuit output conditions, as well as high-side SR configuration. Configurable ringing detection circuitry prevents the MP6908L from false turn-off after \(V_{DS}\) oscillates in discontinuous conduction mode (DCM), or during quasi-resonant operation.

The MP6908L is available in a space-saving TSOT23-6 package.

**FEATURES**

- Wide Output Voltage Range Down to 0V, No Short-Circuit Current Flows through the Body Diode
- Auxiliary Winding for High-Side or Low-Side Rectification is Not Required
- Ringing Detection Prevents False Turn-On in DCM and Quasi-Resonant Operations
- Works with Standard and Logic-Level SR MOSFETs
- Compatible with Energy Star
- 30ns Fast Turn-Off and Turn-On Delay
- 100\(\mu\)A Quiescent Current
- Supports DCM, CCM, and Quasi-Resonant Operation
- Supports Both High-Side and Low-Side Rectification
- Available in a TSOT23-6 Package

**APPLICATIONS**

- USB PD Quick Chargers
- Adapters
- Flyback Power Supplies with Very Low and/or Variable Output Voltages

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. “MPS”, the MPS logo, and “Simple, Easy Solutions” are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

<td>220 °C/W</td>
<td>110 °C/W</td>
</tr>
</tbody>
</table>

### Notes:

1. Exceeding these ratings may damage the device.
2. The maximum allowable power dissipation is a function of the maximum junction temperature, $T_J$ (MAX), the junction-to-ambient thermal resistance, $\theta _{JA}$, and the ambient temperature, $T_A$. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $P_D$(MAX) = ($T_J$(MAX) - $T_A$) / $\theta _{JA}$. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3. The device is not guaranteed to function outside of its operating conditions.
4. Measured on JESD51-7, 4-layer PCB.
### ELECTRICAL CHARACTERISTICS

**VDD = 5V, T_J = -40°C to +125°C, unless otherwise noted.**

Figure 1: Functional Block Diagram
OPERATION

The MP6908L supports discontinuous conduction mode (DCM), continuous conduction mode (CCM), and quasi-resonant mode in flyback converters. The control circuitry controls the gate in forward mode, and turns the gate off when the synchronous rectifier (SR) MOSFET current drops to 0A.

VDD Generation

The capacitor at the VDD pin supplies power to the IC. It can be charged up by either HVC or VD.

When the HVC voltage (V_{HVC}) is below 4.7V, VD charges the external VDD capacitor via a 40mA current source, and regulates VDD to 5V.

When 4.7V < V_{HVC} < 9.7V, VD stops charging VDD. The HVC pin charges VDD via a 70mA current source, and regulates VDD at V_{HVC} - 0.7V. When V_{HVC} > 9.7V, HVC charges VDD via a 70mA current source, and clamps VDD at 9V.

The VDD voltage may be below the under-voltage lockout (UVLO) threshold if VDD is charged through HVC while V_{HVC} rises to 4.7V. This means that the output voltage cannot be below 5V when HVC is connected to the output in a low-side SR configuration (see the Typical System Implementations section on page 11 for more details).

Start-Up and Under-Voltage Lockout (UVLO)

When VDD exceeds 4.2V, the MP6908L passes the under-voltage lockout (UVLO) threshold and the device is enabled. If VDD drops below 4V, the MP6908L enters sleep mode, and V_{GS} remains low.

Turn-On Phase

When V_{DS} drops to about 2V, a turn-on timer begins counting. This turn-on timer can be configured by an external resistor connected to the SLEW pin. If V_{DS} reaches the -86mV turn-on threshold from its original 2V within the time (t_{SLEW}) set by the timer, the MOSFET turns on after a turn-on delay (t_{D-ON}, typically 30ns) (see Figure 2). If V_{DS} reaches -86mV after the timer ends, the gate voltage (V_{G}) remains off. This turn-on timer prevents the MP6908L from false turn-on due to ringing from DCM or quasi-resonant operations.

t_{SLEW} can be calculated with Equation (1):

\[ t_{SLEW} = R_{SLEW} \times \frac{90\text{ns}}{400k\Omega} \] (1)

Figure 2 shows the turn-on/turn-off diagram.

Turn-On Blanking Time

The control circuitry contains a blanking function. When the MOSFET turns on, the control circuit ensures that the on state lasts for a specific period of time. The turn-on blanking time (t_{ON,Blanking}, typically 1.6µs) prevents the device from accidentally turning off due to ringing. However, if V_{DS} rises to between 2V and 3V within the turn-on blanking time, V_{GS} is pulled low immediately.

Conduction Phase

When V_{DS} exceeds the forward voltage drop (V_{FWD}, typically -40mV) according to the decreasing switching current, the MP6908L lowers the gate voltage level to raise the synchronous MOSFET’s on resistance.

With this control scheme, V_{DS} is adjusted to be about -40mV even when the current through the MOSFET is fairly low. This function keeps the driver voltage at a very low level when the synchronous MOSFET is turned off, which boosts the turn-off speed and is especially important in CCM.

Turn-Off Phase

When V_{DS} rises to trigger the turn-off threshold (typically -3mV), the gate voltage is pulled to 0V after a very short turn-off delay (t_{D-OFF}, typically 25ns) (see Figure 2).
Turn-Off Blanking Time

Once the gate driver voltage ($V_{GS}$) is pulled to 0V when $V_{DS}$ reaches the turn-off threshold (typically -3mV), a turn-off blanking time is initiated. During this time, the gate driver signal latches off. The turn-off blanking time completes when $V_{DS}$ exceeds 2V (see Figure 2).
APPLICATION INFORMATION

Slew Rate Detection Function

In DCM, the demagnetizing ringing may force $V_{DS}$ to drop below 0V. If $V_{DS}$ reaches the turn-on threshold during voltage ringing in DCM, an SR controller that does not have the slew rate detection function may turn on the MOSFET by mistake. Figure 3 shows the waveform of this false turn-on. This not only increases power loss, but may also lead to shoot-through if the primary-side FET is turned on within the minimum on time.

![Figure 3: False Turn-On (No Slew Rate Detection)](image)

Note that the ringing slew rate is always much lower when the primary MOSFET is turned off. A false turn-on can be prevented by implementing slew rate detection (see Figure 4). When the slew rate is below the threshold set by $R_{SLEW}$, the IC does not turn on the gate, even when $V_{DS}$ reaches the turn-on threshold.

![Figure 4: Preventing a False Turn-On with Slew Rate Detection](image)

Selecting an External Resistor on VD and HVC

Over-voltage conditions can damage the device, so the application should be designed to guarantee safe operation, especially on the high-voltage pin. One common over-voltage condition is triggered when the SR MOSFET’s body diode turns on, as the forward voltage drop may exceed the negative rating on the VD pin. In this scenario, it is recommended to place an external resistor between VD and the MOSFET drain. Generally, the recommended resistance is 300Ω or greater.

However, this resistor cannot be too large, because a higher-value resistor can compromise the VDD supply and slow down the slew rate on $V_{DS}$ detection. It is not recommended to use a resistor greater than 1kΩ. The resistor value should be determined based on the conditions of the VDD supply and slew rate.

In applications where HVC may also suffer from a negative voltage bias (e.g. in a high-side setup without auxiliary winding), an external resistor between 300Ω and 1kΩ should be connected to HVC.

Typical System Implementations

Figure 5 shows the typical system implementation when the IC’s power supply is derived from the output voltage ($V_{OUT}$). This function is available in low-side rectification.

![Figure 5: Low-Side Rectification](image)

If the MP6908L is used for high-side rectification, a self-supplying system can be achieved through three methods, described below:

Method 1: Figure 6 shows how to implement high-side rectification when HVC is connected to VD. In this scenario, VDD is generated from HVC, then regulated at 9V.
Typically, QG is greater with a smaller R_{DS(ON)}, which lowers the turn-on/turn-off speed and leads to greater power and driver loss. Because V_{DS} is adjusted to be about -40mV during the driving period (when the switching current is fairly small), a MOSFET with a low R_{DS(ON)} is not recommended because the gate driver is pulled low when V_{DS} = -I_{SD} x R_{DS(ON)} exceeds -40mV. The MOSFET’s R_{DS(ON)} does not contribute to the conduction loss. The conduction loss is determined by P_{CON} = V_{DS} x I_{SD}, which is about I_{SD} x 40mV.

To obtain the best efficiency from the MOSFET’s R_{DS(ON)}, the MOSFET should be fully turned on for at least 50% of the SR conduction period. Calculate V_{DS} with Equation (3):

\[ V_{DS} = -I_c \times R_{DS(ON)} = -I_{OUT}/D \times R_{DS(ON)} \leq -V_{FWD} \]  

(3)

Where V_{DS} is drain-source voltage of the MOSFET, D is the duty cycle of the secondary side, I_{OUT} is output current, and V_{FWD} is the forward voltage threshold (about 40mV).

Figure 8 shows the typical waveform of a flyback application. Assume this application has a 50% duty cycle. The MOSFET’s R_{DS(ON)} should not be below 20 / I_{OUT} (mΩ). For example, for a 5A application, R_{DS(ON)} should not be below 4mΩ.

**Figure 8: Typical Waveforms with Synchronous Rectification in a Flyback Application**
PCB Layout Guidelines

Efficient PCB layout is critical for stable operation. For the best results, refer to Figure 9, Figure 10, and Figure 11, and follow the guidelines below:

**Sensing for VD/VSS**

1. Place the sensing connection (VD/VSS) as close as possible to the MOSFET (drain/source).
2. Keep the sensing loop as small as possible.
3. Keep the IC out of the power loop to prevent the sensing loop and power loop from interrupting each other (see Figure 9).

![Figure 9: Voltage Sensing for VD/VSS](image)

- Keep the sensing loop as small as possible
- Keep the sensing loops separated from the power loop

**Gate Driver Loop**

1. Keep the gate driver loop as small as possible to minimize parasitic inductance.
2. Route the driver signal far away from the VD sensing trace on the PCB.

![Figure 10: Layout Example with an SR MOSFET in a TO220 Package](image)

**Layout Examples**

Figure 10 shows a layout example of a 1-layer PCB with a through-hole transformer and an SR MOSFET in a TO220 package. $R_{SN}$ and $C_{SN}$ are the RC snubber network for the SR MOSFET. The sensing loop (VD and VSS to the SR MOSFET) is minimized and kept separate from the power loop. The VDD decoupling capacitor (C2) is placed beside VDD.

Figure 11 shows a layout example of a 1-layer PCB with an SR MOSFET in a PowerPAK/SO8 package, which also has a minimized sensing loop and power loop. This prevents the loops from interfering with each other.

![Figure 11: Layout Example with an SR MOSFET in a PowerPAK/SO8 Package](image)
PACKAGE INFORMATION

TSOT23-6

NOTE:

1) ALL DIMENSIONS ARE IN MILLIMETERS.
2) PACKAGE LENGTH DOES NOT INCLUDE MOLD FLASH, PROTRUSION, OR GATE BURR.
3) PACKAGE WIDTH DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSION.
4) LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.10 MILLIMETERS MAX.
5) DRAWING CONFORMS TO JEDEC MO-193, VARIATION AB.
6) DRAWING IS NOT TO SCALE.
7) PIN 1 IS LOWER LEFT PIN WHEN READING TOP MARK FROM LEFT TO RIGHT (SEE EXAMPLE TOP MARK).
