DESCRIPTION
The MPQ2459 is a monolithic, step-down, switch-mode converter with a built-in power MOSFET. It achieves a 0.5A peak output current over a wide input-supply range with excellent load and line regulation. Current mode operation provides a fast transient response and eases loop stabilization. Fault protections include cycle-by-cycle current limiting and thermal shutdown.

The MPQ2459 requires a minimal number of readily-available, standard, external components. The MPQ2459 is available in a TSOT23-6 package.

FEATURES
- Guaranteed Industrial/Automotive Temp Range Limits.
- 0.5A Peak Output Current
- 1Ω Internal Power MOSFET
- Stable with Low-ESR Ceramic Output Capacitors
- Up to 90% Efficiency
- 0.1μA Shutdown Mode
- Fixed 480kHz Frequency
- Thermal Shutdown
- Cycle-by-Cycle Over-Current Protection
- Wide 4.5V-to-55V Input Operating Range
- Output Adjustable from 0.81V to 0.95×VIN
- Available in a TSOT23-6 Package
- Available in AEC-Q100 Grade 1

APPLICATIONS
- Power Meters
- Distributed Power Systems
- Battery Chargers
- Pre-Regulators for Linear Regulators
- WLED Drivers

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Products, Quality Assurance page.

PACKAGE REFERENCE

ABSOLUTE MAXIMUM RATINGS (1)
Supply Voltage $V_{\text{IN}}$ .......................... $-0.3V$ to $60V$
$V_{\text{SW}}$ ........................................ $-0.3V$ to $V_{\text{IN}}+0.3V$
$V_{\text{BS}}$ ........................................ $V_{\text{SW}} + 6V$
All Other Pins ........................................ $-0.3V$ to $+6V$
Continuous Power Dissipation $(T_A = +25^\circ C)$ (2)
TSOT23-6 .............................................. 0.568W
Junction Temperature ................................ 150°C
Lead Temperature ..................................... 260°C
Storage Temperature ................................. $-65^\circ C$ to $+150^\circ C$

Recommended Operating Conditions (3)
Supply Voltage $V_{\text{IN}}$ .............................. 4.5V to 55V
Output Voltage $V_{\text{OUT}}$ ........................ 0.81V to 0.95$xV_{\text{IN}}$
Operating Junction Temp. ........ $-40^\circ C$ to $+125^\circ C$

Thermal Resistance (4) $\theta_{\text{JA}}$ $\theta_{\text{JC}}$
TSOT23-6 .............................................. 220 .... 110.. °C/W

Notes:
1) Absolute maximum are rated under room temperature unless otherwise noted. Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature $T_{\text{j(MAX)}}$, the junction-to-ambient thermal resistance $\theta_{\text{ja}}$, and the ambient temperature $T_A$. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $P_{\text{D(MAX)}}=(T_{\text{j(MAX)}}-T_A)/\theta_{\text{ja}}$. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device function is not guaranteed outside of the recommended operating conditions.
4) Measured on JESD51-7, 4-layer PCB.
**ELECTRICAL CHARACTERISTICS**

\( V_{\text{IN}} = 12 \text{V}, \ T_J = -40^\circ \text{C} \) to \( +125^\circ \text{C} \), unless otherwise noted. Typical values are at \( T_J=25^\circ \text{C} \).

</tr>
</tbody>
</table>
OPERATION

The MPQ2459 is a current-mode buck regulator — the EA output voltage is proportional to the peak-inductor current.

At the beginning of a cycle, M1 is OFF. The EA output voltage exceeds the current-sense-amplifier output, and the current comparator’s output is LOW. The rising edge of the 480kHz CLK signal sets the RS flip-flop. The flip-flip’s output turns on M1 to connect the SW pin and inductor to the input supply.

The current-sense amplifier senses and amplifies the rising inductor current. The PWM comparator takes the sum of the current-sense amplifier’s output and the ramp compensator and the error amplifier output as its inputs. When the sum of the current sense amplifier’s output and the ramp-compensation signal exceeds the EA output voltage, the RS flip-flop resets and M1 turns OFF. The external Schottky rectifier diode (D1) conducts the inductor current.

If the sum of the current sense amplifier’s output and the slope compensation signal does not exceed the EA output for a whole cycle, then the falling edge of the CLK resets the flip-flop.

The EA output integrates the voltage difference between the feedback and the 0.81V bandgap reference. When \( V_{FB} < 0.81V \), the EA output voltage increases. Since the EA output voltage is proportional to the peak inductor current, an increase in its voltage also increases current delivered to the output.

Enable Control

The MPQ2459 has a dedicated enable control pin EN. With high enough VIN, the chip can be enabled and disabled by EN pin.

Internally a zener diode is connected from EN pin to GND pin. The typical clamping voltage of the zener diode is 7.5V. So VIN can be connected to EN though a high ohm resistor, if the system doesn’t have another logic input acting as enable signal. The resistor needs to be designed to limit the EN pin sink current less than 100\( \mu \)A.

![Figure 1: Functional Block Diagram](image-url)
APPLICATION INFORMATION

Setting the Output Voltage
The external resistor divider sets the output voltage (see Typical Application). Table 1 lists a selection of resistor combinations for common output voltages. The feedback resistor (R2) also sets the feedback loop bandwidth with the internal compensation capacitor (see Figure 1). R1 is then:

\[ R1 = \frac{\frac{R2}{V_{\text{OUT}}}}{0.812V - 1} \]

Inductor Selection

Use an inductor with a DC-current rating at least 25% percent higher than the maximum load current for most applications. Select an inductor with a DC resistance <200m\Omega for highest efficiency. Most designs can use the inductance value calculated from the following equation:

\[ L = \frac{V_{\text{OUT}} \times (V_{\text{IN}} - V_{\text{OUT}})}{V_{\text{IN}} \times \Delta I_L \times f_{SW}} \]

Where \( \Delta I_L \) is the inductor ripple current.

Choose the inductor ripple current at 30% of the maximum load current. The maximum inductor peak current is then:

\[ I_{L(\text{MAX})} = I_{\text{LOAD}} + \frac{\Delta I_L}{2} \]

Under light-load conditions (<100mA), use a larger inductor to improve efficiency.

Input Capacitor Selection

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input-capacitor impedance at the switching frequency should be less than the input-source impedance to prevent high-frequency-switching current from passing through the input. Use ceramic capacitors with X5R or X7R dielectrics because of their low ESR and small temperature coefficients. For most applications, a 4.7\mu F capacitor is sufficient.

Output Capacitor Selection

The output capacitor keeps the output voltage ripple small and ensures feedback loop stability. The output capacitor impedance should be low at the switching frequency. Use ceramic capacitors with X5R or X7R dielectrics for their low ESR characteristics. For most applications, a 22\mu F ceramic capacitor is sufficient.

PCB Layout Guide

PCB layout is very important to achieve stable operation. Please follow these guidelines and use Figure 2 as reference.

1) Keep the switching-current path short and minimize the loop area formed by input capacitor, high-side MOSFET, and Schottky diode.

2) Keep the connection from the Schottky diode to the SW pin and the input power ground as short and wide as possible.

3) Ensure all feedback connections are short and direct. Place the feedback resistors and compensation components as close to the chip as possible.

4) Route SW away from sensitive analog areas such as the FB path.

5) Connect IN, SW, and GND to large copper areas to cool the chip to improve thermal performance and long-term reliability. For single layer PCB, avoid soldering the exposed pad.
External Bootstrap Diode

An external bootstrap diode improve regulator efficiency under the following conditions:

- $V_{OUT} = 5\text{V or 3.3V}$;
- Duty cycle is high: $D = \frac{V_{OUT}}{V_{IN}} > 65\%$

Use an external BST diode from the BST pin to the regulator for best performance, as per Figure 3.

![Figure 2: PCB Layout](image)

**Figure 2: PCB Layout**

![Figure 3: Optional External Bootstrap Diode to Enhance Efficiency](image)

**Figure 3: Optional External Bootstrap Diode to Enhance Efficiency.**

Use an IN4148 external BST diode, and a 0.1µF-1µF. BST capacitor.
