DESCRIPTION

The MPQ2908A is a high-voltage, synchronous, step-down controller that directly steps down voltages from up to 60V. The MPQ2908A uses pulse-width modulation (PWM) current control architecture with accurate cycle-by-cycle current limiting and is capable of driving dual N-channel MOSFETs.

Advanced asynchronous mode (AAM) enables non-synchronous operation to optimize light-load efficiency.

The operating frequency of the MPQ2908A can be programmed by an external resistor or synchronized to an external clock for noise-sensitive applications. Full protection features include precision output over-voltage protection (OVP), output over-current protection (OCP), and thermal shutdown.

The MPQ2908A is available in TSSOP20-EP and QFN-20 (3mmx4mm) packages.

FEATURES

- Wide 4V to 60V Operating Input Range
- Dual N-Channel MOSFET Driver
- 0.8V Voltage Reference with ±1.5% Accuracy Over Temperature
- Low Dropout Operation: Maximum Duty Cycle at 99.5%
- Programmable Frequency Range: 100kHz - 1000kHz
- External Sync Clock Range: 100kHz - 1000kHz
- 180° Out-of-Phase SYNCO Pin
- Programmable Soft Start (SS)
- Power Good (PG) Output Voltage Monitor
- Selectable Cycle-by-Cycle Current Limit
- Output Over-Voltage Protection (OVP)
- Over-Current Protection (OCP)
- Internal LDO with External Power Supply Option
- Programmable Forced CCM and AAM
- Available in TSSOP20-EP and QFN-20 (3mmx4mm) Packages
- Available in a Wettable Flank Package
- Available in AEC-Q100 Grade-1

APPLICATIONS

- Automotive
- Industrial Control Systems

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under quality assurance. “MPS” and “The Future of Analog IC Technology” are registered trademarks of Monolithic Power Systems, Inc.

Thermal Resistance (3)  
TSSOP-20 EP .................................................... 40 °C/W  
QFN-20 (3mmx4mm) ............................................. 48 °C/W  

NOTES:  
1) Absolute maximum ratings are at room temperature unless otherwise noted. Exceeding these ratings may damage the device.  
2) The maximum allowable power dissipation is a function of the maximum junction temperature (TJ) (MAX), the junction-to-ambient thermal resistance (θJA), and the ambient temperature (TA). The maximum allowable continuous power dissipation at any ambient temperature is calculated by Pd(MAX) = (TJ(MAX) - TA) / θJA. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.  
3) Measured on JESD51-7, 4-layer PCB.
## ELECTRICAL CHARACTERISTICS

\( V_{IN} = 24V, \ T_j = -40^\circ C \text{ to } +125^\circ C, \ EN = 2V, \ V_{LIMIT} = 75mV, \) unless otherwise noted.

Figure 1: Block Diagram
TIMING SEQUENCE

Figure 2: Time Sequence
OPERATION

The MPQ2908A is a high-performance, step-down, synchronous, DC/DC controller IC with a wide input voltage range. It implements current-mode control and a programmable switching frequency control architecture to regulate the output voltage with external N-channel MOSFETs.

The MPQ2908A senses the voltage at FB. The difference between the FB voltage (V_{FB}) and an internal 0.8V reference (V_{REF}) is amplified to generate an error voltage on COMP. This is used as the threshold for the current sense comparator with a slope compensation ramp.

Under normal-load conditions, the controller operates in full pulse-width modulation (PWM) mode (see Figure 3). At the beginning of each oscillator cycle, the top gate driver is enabled. The top gate turns on for a period determined by the duty cycle. When the top gate turns off, the bottom gate turns on after a dead time and remains on until the next clock cycle begins.

There is an optional power-save mode for light-load or no-load condition.

**Advanced Asynchronous Mode (AAM)**

The MPQ2908A employs advanced asynchronous mode (AAM) functionality to optimize efficiency during light-load or no-load condition (see Figure 3). AAM is enabled when CCM/AAM is at a low level by connecting an appropriate resistor to SGND to ensure that the AAM voltage (V_{AAM}) is no less than 480mV. See Equation (1):

\[
V_{AAM} (\text{mV}) = I_{AAM} (\mu\text{A}) \times R_{AAM} (\text{k}\Omega) \tag{1}
\]

Where \(I_{AAM}\) is the CCM/AAM output current.

AAM is disabled when CCM/AAM is floating or connected to VCC1. Calculate the CCM/AAM output current (\(I_{AAM}\)) with Equation (2):

\[
I_{AAM} (\mu\text{A}) = \frac{600 \text{ (mV)}}{R_{FREQ} (\text{k}\Omega)} \tag{2}
\]

If AAM is enabled, the MPQ2908A firstly enters non-synchronous operation as long as the inductor current approaches zero at light load. If the load is further decreased or even no load that make COMP voltage below the voltage of AAM threshold at about \(V_{AAM}+V_{OFFSET}\), the MPQ2908A enters AAM mode, where \(V_{AAM}\) is the voltage of CCM/AAM pin and \(V_{OFFSET}\) is about 720mV. In AAM, the internal clock resets whenever \(V_{COMP}\) crosses over the AAM threshold. The crossover time is taken as the benchmark for the next clock cycle. When the load increases and the DC value of \(V_{COMP}\) is higher than the AAM threshold, the operation mode is discontinuous conduction mode (DCM) or continuous conduction mode (CCM), which have a constant switching frequency.

Figure 3: Forced CCM and AAM

**Floating Driver and Bootstrap Charging**

The floating top gate driver is powered by an external bootstrap capacitor (C_{BST}), which is normally refreshed when the high-side MOSFET (HS-FET) turns off. This floating driver has its own under-voltage lockout (UVLO) protection. This UVLO’s rising threshold is 3.05V with a hysteresis of 170mV.

If the BST voltage is lower than the bootstrap UVLO, the MPQ2908A enters constant-off-time mode to ensure that the BST capacitor is high enough to drive the HS-FET.

**VCC1 Regulator and VCC2 Power Supply**

Both the top and bottom MOSFET drivers and most of the internal circuitries are powered by the VCC1 regulator. An internal, low dropout, linear regulator supplies VCC1 power from VIN. Connect a \(\geq 1\mu\text{F}\) ceramic capacitor from VCC1 to PGND.

If VCC2 is left open or connected to a voltage less than 4.7V, an internal 5V regulator supplies power to VCC1 from VIN. If VCC2 is greater than 4.7V, the internal regulator that supplies power to VCC1 from VCC2 is triggered. If VCC2 is between 4.7V and 5V, the 5V regulator is in dropout, and VCC1 approximately equals VCC2. Using the VCC2 power supply allows the VCC1 power to be derived from a high-
efficiency external source, such as one of the MPQ2908A’s switching regulator outputs.

**Error Amplifier (EA)**
The error amplifier compares $V_{FB}$ with the internal 0.8V reference and outputs a current proportional to the difference between the two input voltages. This output current is then used to charge or discharge the external compensation network to form $V_{COMP}$, which is used to control the power MOSFET current. Adjusting the compensation network from COMP to SGND optimizes the control loop for good stability or fast transient response.

**Current Limit Function**
There are three fixed current limit options: 25mV, when ILIM is connected to SGND; 50mV, when ILIM is connected to VCC1; and 75mV, when ILIM is floating.

When the peak value of the inductor current exceeds the set current-limit threshold, the output voltage begins dropping until $FB$ is 37.5% below the reference. The MPQ2908A enters hiccup mode to restart the part periodically. The frequency is lowered when $FB$ is below 0.4V. This protection mode is especially useful when the output is dead-shorted to ground. The average short-circuit current is reduced greatly to alleviate thermal issues. The MPQ2908A exits hiccup mode once the over-current condition is removed.

**Low Dropout Operation**
In low dropout mode, the MPQ2908A is designed to operate in high-side fully on mode for as long as the voltage difference across BST - SW is greater than 3.05V, improving dropout. When the voltage from BST to SW drops below 3.05V, a UVLO circuit turns off the HS-FET. At the same time, the low-side MOSFET (LS-FET) turns on to refresh the charge on the BST capacitor. After the BST capacitor voltage is re-charged, the HS-FET turns on again to regulate the output. Since the supply current sourced from the BST capacitor is low, the HS-FET can remain on for more switching cycles than are required to refresh the BST capacitor, increasing the effective duty cycle of the switching regulator. Low dropout operation makes the MPQ2908A suitable for automotive cold-crank applications.

**Power Good (PG) Function**
The MPQ2908A includes an open-drain power good output that indicates whether the regulator’s output is within ±10% of its nominal value. When the output voltage falls outside of this range, the PG output is pulled low. PG should be connected to a voltage source no more than 5V through a resistor (e.g.: 100kΩ). The PG delay time is 28µs.

**Soft Start (SS)**
Soft start (SS) is implemented to prevent the converter output voltage from overshooting during start-up. When the chip starts up, the internal circuitry generates a soft-start voltage that ramps up from 0V to 1.2V. When it is lower than REF, SS overrides REF, so the error amplifier uses SS as the reference. When SS is higher than REF, REF regains control.

An external capacitor connected from SS to SGND is charged from an internal 4µA current source, producing a ramped voltage. The soft-start time ($t_{SS}$) is set by the external SS capacitor and can be calculated by Equation (3):

$$t_{SS}(\text{ms}) = \frac{C_{SS}(nF) \times V_{REF}(V)}{I_{SS}(\mu A)}$$

Where $C_{SS}$ is the external SS capacitor, $V_{REF}$ is the internal reference voltage (0.8V), and $I_{SS}$ is the 4µA SS charge current. There is no internal SS capacitor. SS is reset when a fault protection other than OVP occurs.

**Output Over-Voltage Protection (OVP)**
The output over-voltage is monitored by $V_{FB}$. If $V_{FB}$ is typically 15% higher than the reference, the MPQ2908A enters discharge mode. The HS-FET turns off, and the LS-FET turns on. The LS-FET remains on until the reverse current limit is triggered. The LS-FET then turns off, and the inductor current increases to 0. The LS-FET is turned on again after ZCD is triggered. The MPQ2908A works in discharge mode until the over-voltage condition is cleared.
EN/SYNC Control
The MPQ2908A has a dedicated enable (EN/SYNC) control that uses a bandgap-generated precision threshold of 1.22V. By pulling EN/SYNC high or low, the IC can be enabled or disabled. To disable the part, EN/SYNC must be pulled low for at least 40µs.

Tie EN/SYNC to VIN through a resistor divider (R16 and R17) to program the VIN start-up threshold (see Figure 4). The EN/SYNC threshold is 1.09V (falling edge), so the VIN UVLO threshold is 1.09V x (1 + R16/R17).

Otherwise, if VIN ≤ 52V, EN/SYNC can be connected to VIN directly. If VIN ≥ 52V, a ≥50kΩ pull-up resistor is needed to prevent EN/SYNC from breaking down.

Figure 4: EN Resistor Divider
The device can be synchronized to an external clock ranging from 100kHz up to 1000kHz through EN/SYNC. The internal clock rising edge is synchronized to the external clock rising edge. The pulse width (both on and off) of the external clock signal should be no less than 100ns.

SYNCO Function
The SYNCO pin outputs a default 180° phase shifted clock when MPQ2908A works in CCM. This function allows two devices operate in same frequency but 180°out of phase to reduce the total input current ripple, so a smaller input bypass capacitor can be used.

Under-Voltage Lockout (UVLO)
Under-voltage lockout (UVLO) is implemented to protect the chip from operating at an insufficient input supply voltage. The MPQ2908A UVLO rising threshold is about 4.5V, while its falling threshold is a consistent 3.7V.

Thermal Protection
Thermal protection prevents damage to the IC from excessive temperatures. The die temperature is monitored internally until the thermal limit is reached. When the silicon die temperature is higher than 170°C, the entire chip shuts down. When the temperature is lower than its lower threshold (typically 20°C), the chip is enabled again.

Start-Up and Shutdown
If both VIN and EN/SYNC are higher than their respective thresholds, the chip starts up. The reference block starts first, generating stable reference voltages and currents. The internal regulator is then enabled. The regulator provides a stable supply for the remaining circuitry.

Three events can shut down the chip: EN low, VIN low, and thermal shutdown. During the shutdown procedure, the signal path is blocked first to avoid any fault triggering. VCOMP and the internal supply rail are then pulled down. The floating driver is not subject to this shutdown command.

Pre-Bias Start-Up
If SS is less than FB at start-up, the output has a pre-bias voltage, and neither TG nor BG is turned on until SS is greater than FB.
APPLICATION INFORMATION

Setting the Output Voltage

The external resistor divider is used to set the output voltage (see Figure 5).

![Figure 5: External Resistor Divider](image)

If \( R_8 \) is known, then \( R_9 \) can be calculated with Equation (4):

\[
R_9 = \frac{R_8 \cdot V_{OUT}}{0.8V - 1} \quad (4)
\]

Table 1 lists the recommended feedback resistor values for common output voltages.

Setting Current Sensing

The MPQ2908A has three fixed current limit options: 25mV, when \( ILIM \) is connected to \( SGND \); 50mV, when \( ILIM \) is connected to \( VCC1 \); and 75mV, when \( ILIM \) is floating. Ensure that the application can deliver a full load of current over the full operating temperature range when setting \( ILIM \).

The current sense resistor (\( R_{SENSE} \)) monitors the inductor current. Its value is chosen based on the current limit threshold. The relationship between the peak inductor current (\( I_{pk} \)) and \( R_{SENSE} \) can be calculated with Equation (5):

\[
R_{SENSE} = \frac{V_{LIMIT}}{I_{pk}} \quad (5)
\]

A higher \( R_{SENSE} \) value increases power loss across it. Considering the output current, efficiency and \( ILIM \) threshold, the recommended value for \( R_{SENSE} \) is between 7mΩ and 50mΩ.

Programmable Switching Frequency

Consider different variables when choosing the switching frequency. A high frequency increases switching losses and gate charge losses, while a low frequency requires more inductance and capacitance, resulting in larger real estate and higher cost. Setting the switching frequency is a trade-off between power loss and passive component size. In noise-sensitive applications, the switching frequency should be out of a sensitive frequency band.

The MPQ2908A’s frequency can be programmed from 100kHz to 1000kHz with a resistor from \( FREQ \) to \( SGND \) (see Table 2). The value of \( R_{FREQ} \) for a given operating frequency can be calculated with Equation (6):

\[
R_{FREQ}(k\Omega) = \frac{20000}{f_0(kHz)} - 1 \quad (6)
\]

VCC Regulator Connection

VCC1 can be powered from both VIN and VCC2. If connecting VCC2 to an external power supply to improve the overall efficiency, VCC2 should be larger than 4.7V but smaller than 12V (see Figure 6).

![Figure 6: Internal Circuitry of VCC2](image)
If \( V_{OUT} \) is higher than 4.7V but less than 12V, \( V_{CC2} \) can be connected to \( V_{OUT} \) directly (see Figure 7).

**Figure 7: Configuration of VCC2 Connecting to \( V_{OUT} \)**

**Selecting the Inductor**

An inductor with a DC current rating at least 25% higher than the maximum load current is recommended for most applications. A larger-value inductor results in less ripple current and a lower output ripple voltage. However, the larger-value inductor also has a larger physical size, higher series resistance, and lower saturation current. Choose the inductor ripple current to be approximately 30% of the maximum load current. The inductance value can be then be calculated with Equation (7):

\[
L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I \times f_s}
\]  

(7)

Where \( V_{OUT} \) is the output voltage, \( V_{IN} \) is the input voltage, \( f_s \) is the 300kHz switching frequency, and \( \Delta I \) is the peak-to-peak inductor ripple current.

The maximum inductor peak current can be calculated with Equation (8):

\[
I_{L(\text{MAX})} = I_{LOAD} + \frac{\Delta I}{2}
\]  

(8)

Where \( I_{LOAD} \) is the load current.

**Selecting the Input Capacitor**

Since the input capacitor absorbs the input switching current, it requires an adequate ripple current rating. The selection of the input capacitor is based mainly on its maximum ripple current capability. The RMS value of the ripple current flowing through the input capacitor can be calculated with Equation (9):

\[
I_{RMS} = \frac{I_{LOAD} \times V_{OUT} \times (1 - \frac{V_{OUT}}{V_{IN}})}{V_{IN}}
\]  

(9)

The worst-case condition occurs at \( V_{IN} = 2V_{OUT} \), shown in Equation (10):

\[
I_{RMS} = \frac{2I_{LOAD}}{2}
\]  

(10)

The input capacitor must be capable of handling this ripple current.

**Output Capacitor Selection**

The output capacitor impedance should be low at the switching frequency. The output voltage ripple can be estimated with Equation (11):

\[
\Delta V_{OUT} = \frac{V_{OUT}}{f_s \times L} \times \left( 1 - \frac{V_{OUT}}{V_{IN}} \right) \times \left( R_{ESR} + \frac{1}{8 \times f_s \times C_o} \right)
\]  

(11)

Where \( C_o \) is the output capacitance value, and \( R_{ESR} \) is the equivalent series resistance (ESR) value of the output capacitor.

For tantalum or electrolytic capacitor application, the ESR dominates the impedance at the switching frequency. The output voltage ripple can be approximated with Equation (12):

\[
\Delta V_{OUT} = \frac{V_{OUT}}{f_s \times L} \times \left( 1 - \frac{V_{OUT}}{V_{IN}} \right) \times R_{ESR}
\]  

(12)

**Power MOSFET Selection**

Two N-channel MOSFETs must be selected for the controller: one for the high-side switch, and one for the low-side switch.

The driver level of the high-side and low-side MOSFETs is 5V, so the threshold voltage (\( V_{th} \)) of the selected MOSFETs must be no higher than this value.

The input voltage (\( V_{DS} \)), continuous drain current (\( I_{D} \)), on resistance (\( R_{DS(ON)} \)), total gate charge (\( Q_g \)), and thermal related parameters should be considered when choosing the power MOSFETs.

\( V_{DS} \) of the chosen MOSFETs should exceed the maximum applied voltage between the drain and source in the application, which is \( V_{IN(\text{MAX})} \) plus additional rings on the switch node.
The MOSFET's power dissipations can be calculated with Equation (13) and Equation (14):

\[
P_{HS} = I_{OUT}^2 \times R_{ON-HS} \times \frac{V_{OUT}}{V_{IN}} + \frac{1}{2} \times V_{IN} \times I_{OUT} \times (t_r + t_f) \times f_{SW} + Q_{g-HS} \times f_{SW} \times V_{driver}
\]

\[
P_{LS} = I_{OUT}^2 \times R_{ON-LS} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) + Q_{g-LS} \times f_{SW} \times V_{driver} + V_{DROP} \times I_{OUT} \times (t_{dead1} + t_{dead2}) \times f_{SW}
\]

Where \( R_{ON-HS} \) and \( R_{ON-LS} \) are the on resistance of the HS-FET and LS-FET, \( t_r \) and \( t_f \) are the rising and falling time of the switch, \( Q_{g-HS} \) and \( Q_{g-LS} \) are the total gate charge of the HS-FET and LS-FET, \( V_{driver} \) is the gate driver voltage (which is provided by VCC1), \( V_{DROP} \) is the LS-FET body diode forward voltage, \( t_{dead1} \) is the dead time between the HS-FET turning off and the LS-FET turning on, and \( t_{dead2} \) is the dead time between the LS-FET turning off and the HS-FET turning on.

Ensure that the thermal caused by the power loss on the MOSFETs does not exceed the allowed maximum thermal of the selected MOSFETs.

**Schottky Selection**

The diode between SW and PGND (shown as D2 in Figure 11) is used to absorb spike and store charges during the dead time and protect the body diode of the LS-FET. Considering the size and power loss during the dead time, a 1A - 3A Schottky diode is recommended.

**BST Charge Diode and Resistor Selection**

An external BST diode can enhance the efficiency of the regulator when the duty cycle is high. A power supply between 2.5V and 5V can be used to power the external bootstrap diode. VCC1 or VOUT is recommended to be this power supply in the circuit (see Figure 8).

**Figure 8: External Bootstrap Diode and Resistor**

The recommended external BST diode is IN4148, and the recommended BST capacitor value is 0.1\( \mu \)F to 1\( \mu \)F.

A resistor in series with the BST capacitor (\( R_{BST} \)) can reduce the SW rising rate and voltage spikes. This helps enhance EMI performance and reduce voltage stress at a high \( V_{IN} \). A higher resistance is better for SW spike reduction but compromises efficiency. To make a tradeoff between EMI and efficiency, a \( \leq 20\Omega \) \( R_{BST} \) is recommended.

**Compensation Components**

The MPQ2908A employs current-mode control for easy compensation and fast transient response. COMP is the output of the internal error amplifier and controls system stability and transient response. A series resistor-capacitor (R-C) combination sets a pole zero combination to control the control system's characteristics. The DC gain of the voltage feedback loop can be calculated with Equation (15):

\[
A_{VDC} = R_{LOAD} \times G_{CS} \times A_0 \times \frac{V_{FB}}{V_{OUT}}
\]

Where \( A_0 \) is the error amplifier voltage gain (3000V/V), \( G_{CS} \) is the current sense transconductance \( 1/(12 \times R_{SENSE}) \) (A/V), and \( R_{LOAD} \) is the load resistor value.
The system has two important poles: one from the compensation capacitor (C6) and the output resistor of the error amplifier, and the other from the output capacitor and the load resistor (see Figure 9). These poles can be calculated with Equation (16) and Equation (17):

\[ f_{p1} = \frac{G_m}{2\pi C6 A_o} \]  
\[ f_{p2} = \frac{1}{2\pi C6 R_{load}} \]  

Where \( G_m \) is the error amplifier transconductance (500μA/V), and \( C_o \) is the output capacitor. The system has one important zero due to the compensation capacitor and the compensation resistor (R5) and can be calculated with Equation (18):

\[ f_{z1} = \frac{1}{2\pi C6 R5} \]  

The system may have another significant zero if the output capacitor has a large capacitance or high ESR value, and can be calculated with Equation (19):

\[ f_{ESR} = \frac{1}{2\pi C6 R_{ESR}} \]  

In this case, a third pole set by the compensation capacitor (C7) and the compensation resistor can compensate for the effect of the ESR zero. This pole is calculated with Equation (20):

\[ f_{p3} = \frac{1}{2\pi C7 R5} \]  

The goal of the compensation design is to shape the converter transfer function for a desired loop gain. The system crossover frequency where the feedback loop has unity gain is important, since lower crossover frequencies result in slower line and load transient responses, and higher crossover frequencies lead to system instability. Set the crossover frequency to ~0.1xfSW.

Follow the steps below to design the compensation.

1. Choose R5 to set the desired crossover frequency with Equation (21):

\[ R5 = \frac{2\pi C6 f_c V_{OUT}}{G_m G_{CS} V_{FB}} \]  

Where \( f_c \) is the desired crossover frequency.

2. Choose C6 to achieve the desired phase margin. For applications with typical inductor values, set the compensation zero \( (f_{z1}) < 0.25xf_c \) to provide a sufficient phase margin. C6 is then calculated with Equation (22):

\[ C6 > \frac{4}{2\pi R5 f_c} \]  

3. C7 is required if the ESR zero of the output capacitor is located at <0.5xfSW, or Equation (23) is valid:

\[ \frac{1}{2\pi C6 R_{ESR}} < \frac{f_{SW}}{2} \]  

If this is the case, use C7 to set the pole \( (f_{p3}) \) at the location of the ESR zero. Determine C7 with Equation (24):

\[ C7 = \frac{C6 R_{ESR}}{R5} \]
PCB Layout Guidelines
Efficient PCB layout, especially for input capacitor placement, is critical for stable operation. A four-layer layout is strongly recommended to achieve better thermal performance. For best results, refer to Figure 10 and follow the guidelines below.

1. Place the MOSFETs as close as possible to the device.
2. Make the sense lines (the red lines in Inner Layer 2 of Figure 10) run close together using a Kelvin connection to reduce the line drop error.
3. Use a large ground plane to connect to PGND directly.
4. Add vias near PGND if the bottom layer is a ground plane.
5. Ensure that the high-current paths at PGND and VIN have short, direct, and wide traces.
6. Place the ceramic input capacitor, especially the small package size (0603) input bypass capacitor, as close to IN and PGND as possible to minimize high-frequency noise.
7. Keep the connection of the input capacitor and IN as short and wide as possible.
8. Place the VCC1 capacitor as close to VCC1 and SGND as possible.
9. Route SW and BST away from sensitive analog areas such as FB.
10. Place the feedback resistors close to the chip to ensure that the trace which connects to FB is as short as possible.
11. Use multiple vias to connect the power planes to the internal layers.

PACKAGE INFORMATION

TSSOP-20 EP

NOTE:
1) ALL DIMENSIONS ARE IN MILLIMETERS
2) PACKAGE LENGTH DOES NOT INCLUDE MOLD FLASH
3) PACKAGE WIDTH DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSION.
4) LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.10 MILLIMETERS MAX
5) DRAWING CONFORMS TO JEDEC MO-153, VARIATION A1
6) DRAWING IS NOT TO SCALE
PACKAGE INFORMATION (continued)

QFN-20 (3mmx4mm)
Non-Wettable Flank

DETAIL A

NOTE:

1) ALL DIMENSIONS ARE IN MILLIMETERS.
2) EXPOSED PADDLE SIZE DOES NOT INCLUDE MOLD FLASH.
3) LEAD COPLANARITY SHALL BE 0.08 MILLIMETERS MAX.
4) JEDEC REFERENCE IS MO-220.
5) DRAWING IS NOT TO SCALE.

RECOMMENDED LAND PATTERN

PACKAGING INFORMATION (continued)

QFN-20 (3mmx4mm)
Wettable Flank

NOTE:
1) THE LEAD SIDE IS WETTABLE.
2) ALL DIMENSIONS ARE IN MILLIMETERS.
3) EXPOSED PADDLE SIZE DOES NOT INCLUDE MOLD FLASH.
4) LEAD COPLANARITY SHALL BE 0.08 MILLIMETERS MAX.
5) JEDEC REFERENCE IS MO-220.
6) DRAWING IS NOT TO SCALE.

RECOMMENDED LAND PATTERN
