DESCRIPTION
The MPQ5480 is a monolithic power management solution for wearable device.

It contains a USB compatible, constant current/constant voltage charger along with a high efficiency synchronous step down regulator.

The MPQ5480 also features cell protection and a separate power switch for powering additional power devices.

The hysteresis control scheme provides fast transient response and eases loop stabilization. Fault condition protection includes cycle by cycle current limiting, output short protection and thermal shutdown.

The MPQ5480 requires a minimum number of external components and is available in a WLCSP-16 (1.7mmx1.7mm) package.

FEATURES
- Wide 4V to 6V Charger Input Range
- 100mA DC-DC Output Current
- Feedback Voltage Accuracy: 1%
- 1.22V Default Output Voltage
- Programmable Output Voltage via Resistor Divider (For \(V_{\text{OUT}}>1.22V\))
- Integrated Push-button De-bouncer
- Cycle-by-Cycle Over Current Protection
- On Die Thermal Protection
- Stable with Low ESR Output Ceramic Capacitors
- Available in a WLCSP-16 (1.7mmx1.7mm) Package

APPLICATIONS
- Wearable Device
- Other Battery Based Portable Device

TYPICAL APPLICATION

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance.

WLCSP-16 (1.7mmx1.7mm)
**ABSOLUTE MAXIMUM RATINGS** \(^{(1)}\)

Charger input (V<sub>CH</sub>) .............................................................................................................. -1V to 7V
Battery supply voltage (V<sub>BATT</sub>) ............................................................. -0.3V to 5V
Switch pin voltage (V<sub>SW</sub>) .................................................. -0.3V to V<sub>BATT</sub>+0.3V
All other pins ........................................................................................................... -0.3V to 6.5V
Continuous power dissipation (T<sub>A</sub> = +25°C) \(^{(2)}\)
........................................................................................................................... 1.3W
Junction temperature .................................................................................. 150°C
Lead temperature ......................................................... -65°C to 150°C
Storage temperature ................................................................... -65°C to 150°C

**Recommended Operating Conditions**

Charger input (V<sub>CH</sub>) ................................................................. 4V to 6V
Battery supply voltage (V<sub>BATT</sub>) .................. 2.5V to 4.8V
Operating junction temp. (T<sub>J</sub>) .......................... -40°C to +125°C

**Thermal Resistance** \(^{(3)}\) \(\theta_{JA} \quad \theta_{JC}\)

WLCSP-16 (1.7mmx1.7mm) ........................................... 95 ....... 1 ....... °C/W

**Notes:**

1) Absolute maximum ratings are rated under room temperature unless otherwise noted. Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub> (MAX), the junction-to-ambient thermal resistance \(\theta_{JA}\), and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub> (MAX) = (T<sub>J</sub> (MAX) - T<sub>A</sub>)/\(\theta_{JA}\). Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) Measured on JESD51-7, 4-layer PCB.

Figure 1: Functional Block Diagram
OPERATION

MPQ5480 is a complete power management solution for Lithium-Ion battery powered device. It integrates a CC/CV charger, cell protection function, high efficiency synchronous buck regulator and a push-button controller.

MPQ5480 has following modes:

Shutdown: When $V_{BATT} < V_{th\_UVLO}$, system draws only leakage current from battery and re-activation is only possible by connecting a charger.

Charging: Charger is connected to system. DC/DC, Vo2 and push-button are de-activated. After charger is removed system will be in Normal Operation OFF condition.

Normal Operation (ON/OFF): $V_{BATT} > V_{th\_UVLO}$ and no charger is connected. In this mode the system can be turned ON or OFF by toggling the push-button.

Charger

The MPQ5480 integrated linear charger provides CC/CV charging algorithms. It changes charge modes automatically depending on the battery status. A typical charging profile is shown on Figure 2.

When battery voltage falls below the trickle falling threshold ($V_{th\_trich}$ with ~180mV hysteresis), the charging current is limited to 10% of the programmed value to trickle charge the fully depleted battery. After the battery voltage reaches the trickle rising threshold ($V_{th\_trich}$), the charger begins to charge at a constant current of the programmed value ($I_{CHG}$). $I_{CHG}$ is typically set to C/2. This is referred to as Constant Current (CC) mode. Once the battery voltage reaches CV-Level $V_{CV}$ (e.g. 4.10V), the charger will operate in Constant Voltage (CV) mode until the battery is fully charged. Charging is terminated when the current into the battery falls to 10% of the defined charging current $I_{CHG}$ or the charge termination timer (3.6h) expires.

MPQ5480 also provides an ON Chip temperature sensor to prevent charging outside normal battery temperature limits. The charger will only start to charge when the die temperature is between 6°C and 49°C.

Figure 2: Typical Charging Profile

The defined charging current, $I_{CHG}$ is programmed through resistor $R_{ICHG}$ from ICHG pin to GND. The relationship of the charging current and $R_{ICHG}$ is shown in Table 1 and Figure 3.

Figure 3: $I_{CHG}$ vs. $R_{ICHG}$
Dead Battery Detection
When the cell voltage is below trickle charge level, the system will therefore start with trickle charge. If the cell voltage will not rise above the threshold within 7 minutes, the IC will consider the battery is dead and stop charging.

High Efficiency DC/DC
The core of the MPQ5480 is a high efficiency integrated synchronous buck to step down the voltage of the battery to a regulated voltage. The peak inductor current is always limited to prevent the damage of the small cell. The default output voltage is set to 1.22V. The max output voltage ripple is controlled to be <80mV for load transients of 45mA/5ms. The over shoot voltage during the startup is controlled to be <150mV. The max output capacitor is up to 250uF. The DC/DC converter is controlled through the current limit comparator, output feedback comparator and the zero current comparator. If VO is below the reference and the min off time is passed, the high-side MOSFET (HS-FET) turns on, and then the current through the HS-FET is sensed and compared with the current limit threshold. When the current reaches this threshold, the HS-FET turns off immediately. Then the low-side MOSFET (LS-FET) turns on to discharge the inductor current. The LS-FET turns off when zero inductor current is detected. The converter is entering DCM mode and waiting for VO dropping below the threshold. When VO drops below the threshold, the HS-FET turns on again and starts another cycle. The converter is normally worked as DCM; while during the load transient, it is able to go into CCM for a fast transient response. This operation will minimize the output cap and still always limit the max input current close to peak current to protect the battery cell. The peak current is set by the resistor on the IPK pin. The relationship of the peak current and RIPK is shown in Table 2 and Figure 5. There is an internal 2kΩ resistor in series with RIPK to ensure the peak current not too large even RIPK=0.

\[
V_0 = \left[1 + R_{UP} / (R_{DOWN} / R_S)\right] \times VOUT
\]

Where \(R_S\) is the sum of internal FB resistor divider (\(R_S=900\)kohm), VOUT is the 1.22V default output.

The output voltage (\(V_0\)) can also be set by adding an external resistive voltage divider from the output to VOUT pin (as shown in Figure 4).

The effective switching frequency with a given load can be influenced by the inductor value and IPK setting.

### Figure 4: Output voltage set by resistor dividers

To get the desired output voltage, divider resistors can be chosen through below equation:

\[
V_0 = \left[1 + R_{UP} / (R_{DOWN} / R_S)\right] \times VOUT
\]

Where \(R_S\) is the sum of internal FB resistor divider (\(R_S=900\)kohm), VOUT is the 1.22V default output.

The DC/DC converter is controlled through the current limit comparator, output feedback comparator and the zero current comparator. If \(V_0\) is below the reference and the min off time is passed, the high-side MOSFET (HS-FET) turns on, and then the current through the HS-FET is sensed and compared with the current limit threshold. When the current reaches this threshold, the HS-FET turns off immediately. Then the low-side MOSFET (LS-FET) turns on to discharge the inductor current. The LS-FET turns off when zero inductor current is detected. The converter is entering DCM mode and waiting for \(V_0\) dropping below the threshold. When \(V_0\) drops below the threshold, the HS-FET turns on again and starts another cycle. The converter is normally worked as DCM; while during the load transient, it is able to go into CCM for a fast transient response. This operation will minimize the output cap and still always limit the max input current close to peak current to protect the battery cell. The peak current is set by the resistor on the IPK pin. The relationship of the peak current and RIPK is shown in Table 2 and Figure 5. There is an internal 2kΩ resistor in series with RIPK to ensure the peak current not too large even RIPK=0.

### Figure 5: IPK vs. RIPK

The effective switching frequency with a given load can be influenced by the inductor value and IPK setting.
During the light load, the switching frequency will decrease. To prevent the frequency entering the audible band, a proper inductor is needed (when $I_{PK}$ and load is fixed) to keep switching frequency over 20kHz.

The DC/DC features internal soft starts function. The soft start time is about 0.3ms. The soft start voltage ($V_{SS}$) slowly ramps up from 0V to the internal reference ($V_{REF}$). When $V_{SS}$ is lower than $V_{REF}$, $V_{SS}$ overrides $V_{REF}$ as the reference. When $V_{SS}$ exceeds $V_{REF}$, $V_{REF}$ acts as the reference. With large output cap, it is possible that $V_o$ is not charged to the regulated voltage during the soft start time. At this condition, the converter will charge the output cap with its max current as set by $I_{PK}$.

Thermal shutdown is implemented to prevent the chip from operating at exceedingly high temperatures. When the die temperature exceeds the upper threshold, the entire chip shuts down. When the die temperature is recovered, the system will be in Normal Operation OFF condition.

**Push-button Control**

The push-button is a toggle switch input: If the IC is off, a push action of longer than $T_{PUSH}$ will cause the IC to turn on. Additional pressing of longer than $T_{PUSH}$ will cause the IC to turn off. The push-button controller contains an internal timer, and a flip-flop. The debounce timer will start counting when the output of the debouncer is equal to the EN. And resets whenever the EN pin bounce. The output flips when the time is out. When the output of the debouncer is not equal to the EN, the timer will start to count as the idle mode delay timer. When time elapsed, the debouncer goes to idle mode and consumes no power until the EN pin bounces again.

The output of the debouncer then feeds the signal to a flip-flop which is triggered by rising edge to enable/disble the DC/DC and the Vo2 MOSFET.

The output of the flip-flop is forced to low when $V_{CH}$ is connected ($V_{CH} > 3.8V$). it forces the DC/DC and Vo2 MOSFET to be disabled. Toggling the push-button cannot turn on the DC/DC and the Vo2 MOSFET at this condition. When charger is removed ($V_{CH} < 3.5V$), the output of the flip-flop will stay low, but will flip when push-button is toggled. The push-button is also disabled when battery voltage is below under-voltage lockout threshold. $T_{PUSH} > 2.2$s, OFF $\rightarrow$ ON; and $T_{PUSH} > 2.2$s, ON $\rightarrow$ OFF.

Push times shorter than $T_{PUSH}$ will be ignored by MPQ5480.

**Battery Under-Voltage Protection**

The capacitor on the EOL pin acts as a low pass filter to obtain the average voltage of the battery over 1ms (which is depending on the EOL capacitor value). If the low pass filtered battery voltage is lower than $V_{th_UVLO}$, the DC/DC will be disabled. The MOSFET connected to the Vo2 will also be turned off and the system will be in shutdown mode. Push-button is inactive in this condition. MPQ5480 is latched in this shutdown mode until a valid external power source is connected to CH pin ($V_{CH} > 3.8V$). There is no UVLO hysteresis.

**System Extension**

MPQ5480 offers a Vo2 pin to extend the power system for more complex application. Additional DC/DC converter can be connected to Vo2 to draw the power from the battery while sharing the power management function of MPQ5480.

When the battery voltage is lower than $V_{th_UVLO}$, the MOSFET between Vo2 and $V_{BATT}$ will be turned off. During the charge, when $V_{CH} > 3.8V$, the MOSFET is also turned off.

The extension switch also integrates the over current protection and short circuit protection in case too much current is drawn from the battery resulting in cell damage.

When the output current is sensed higher than the over current threshold ($> 3.8 \times I_{CHG}$) but lower than the short circuit threshold ($> 5 \times I_{CHG}$), the switch will turn off after the over current detection delay time ($T_{DC}=9ms$). When the output current is higher than short circuit threshold ($> 5 \times I_{CHG}$), the switch will turn off after the short circuit detection delay time ($T_{DSC}=300\mu s$). The switch will turn on again after the auto retry time delay ($T_{AR}=75ms$). In case that the battery voltage is lower than $V_{th_UVLO}$, the auto retry will not happen.
The timing charts are shown in Figure 6 and Figure 7.

Four events can shut down Vo2: toggling the push-button, charger is connected, $V_{\text{BATT}} < V_{\text{th_UVLO}}$, and thermal shutdown.
