

# MEZS7-1SDAPowerBank

## All-In-One 3A Battery Charger with 3A Boost Current Solution Module

### DESCRIPTION

The MEZS7-1SDAPowerBank is a complete power bank solution module using the MP2632, which includes a buck charger with BC1.2 detection, integrated boost with two separate outputs, and a 4-LED indicator for battery state of charge.

The solution module uses a form-fitting board and supports two operating modes — charge mode and boost mode — to allow system and battery power management based on the state of the input.

When a 5V USB input power is present, the board charges a single-cell battery with a max charge current of 3A. In the absence of an input source, the solution module switches to boost mode through the PB pin to power the SYS output from the battery with a max current of up to 3A for two USB ports. The distribution of current between the two USB ports is dependent on the load at each port.

The solution module provides four LED drivers to achieve the voltage-based fuel gauge indication and distinguish charge mode from boost mode. To guarantee safe operation, the solution module offers input over-voltage protection, battery over-voltage protection, thermal shutdown, battery temperature monitoring, and a timer to prevent prolonged charging of a dead battery.

### ELECTRICAL SPECIFICATIONS

Parameter	Symbol	Value	Units
<b>Charge Mode</b>			
Input voltage range	$V_{IN}$	4.55 to 6	V
Charge-full voltage	$V_{BATT\_FULL}$	4.2, 4.35, 4.45	V
Charge current	$I_{CHG}$	3	A
Input current limit	$I_{IN\_LIM}$	2.7	A
<b>Boost Mode</b>			
Battery voltage	$V_{BATT}$	3 to 4.45	V
SYS voltage regulation	$V_{SYS}$	5	V
SYS output current limit	$I_{SYS}$	3	A

### FEATURES

- 4.55V to 6V Operating Input Voltage Range
- Power Management Function Includes Integrated Input Current Limit and Input Voltage Regulation
- Up to 3A Charge Current
- Selectable 4.45V/4.35V/4.2V Charge Voltage with 0.5% Accuracy
- Battery Temperature Monitoring
- 4 LED Drivers for Battery Fuel Gauge Indication
- Timer Backup Protection
- Battery Reverse Leakage Blocking
- Reverse Boost Operation for Powering the System
- Up to 94% 5V Boost Mode Efficiency at 3A with BATT = 4.5V
- Up to 3A Output Current Limit in Boost Mode

### APPLICATIONS

- Battery Backup Applications
- Dual-Output Power Bank Applications for Smartphones, Tablets, and Other Portable Devices

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

Board Number	MPS IC Number
MEZS7-1SDAPowerBank	MP2632GR

## QUICK START GUIDE

This is a solution module for the MP2632, a standalone switch-mode battery charge management and system power path management device with integrated reverse directional boost from BATT to SYS. The solution module's layout accommodates most commonly used capacitors. The default function of this solution module is preset at charge mode, and the charge-full voltage is preset to 4.2V for a single-cell Li-ion battery.

### Charge Mode Settings

#### 1. Input Current Limit

The input current limit can be set slightly below the input source's maximum current rating. When the input current reaches this limit, the charge current decreases to keep the input current constant at the limit value to initially power the system. The resistor connected to the ILIM pin ( $R_{ILIM}$ ) programs this limit. To set the input current limit at 2.7A, use an  $R_{ILIM}$  of 14.7k $\Omega$ . Calculate  $I_{ILIM}$  with Equation (1):

$$I_{ILIM}(A) = \frac{40(k\Omega)}{R_{ILIM}(k\Omega)} \quad (1)$$

#### 2. Charge-Full Voltage

The default charge-full voltage on this solution module is set at 4.2V by floating R1 and R2. The setting can be modified according to Table 1.

**Table 1: R1 and R2 Settings**

R1	R2	Charge-Full Voltage (V)
Float	Float	4.2
Float	0 $\Omega$	4.35
0 $\Omega$	Float	4.45

#### 3. Charge Current

The charge current can be programmed via both RS1 and  $R_{ISET}$ . With given RS1 = 10m $\Omega$ , determine the charge current using Equation (2):

$$I_{CHG}(A) = \frac{1500}{R_{ISET}(k\Omega) \times RS1(mA)} \quad (2)$$

For 3A charge current, the given  $R_{ISET}$  is 49.9k $\Omega$ .

### Boost Mode

#### 1. System Output Current Limit

Set the system output current limit in boost mode for the MP2632 to operate like a standard adapter. Set the output current limit using Equation (3):

$$I_{OLIM}(A) = \frac{1500}{R_{OLIM}(k\Omega) \times RS1(m\Omega)} \quad (3)$$

For 3A output current limit, the given  $R_{OLIM}$  is 49.9k $\Omega$ .

For additional information on MP2632 operation, refer to the MP2632 datasheet.

## EQUIPMENT REQUIREMENT

Evaluation requires the following equipment:

4. A USB cable with an adapter or any USB port with load capability (for the charge input) can be used for the solution module. If a certain operation state cannot be tested, an external wire can be added to connect a power source with 6V/3A capability.
5. Battery simulator or a single-cell battery pack. The battery simulator's output rating should be greater than 4.5V/7.0A. When using a real battery pack, review all precautions on the battery manufacturer's datasheet and ensure the charger's setting does not exceed the battery's absolute maximum specifications.
6. E-load or real smartphone. The e-load capability should be greater than 5V/3A.
7. An oscilloscope with a single voltage probe and a single current probe.
8. An multi-meter.

### Charge Function

1. Attach the positive and negative ends of the battery to the "+" and "-" terminals, respectively. If using a battery simulator, preset the voltage to 3.8V (typical value) first.
2. Use the USB cable and adapter or any USB port with load capability.

**Figure 1: Set-Up for Charge Mode**

3. Connect the adapter or USB port to the solution module through USB1 to start the charge. Use the oscilloscope to verify that the 3A charge current is being delivered to the battery. The charge current can be a different value under the following conditions:
  - a. The charge current is limited by the input current limit.

The IC features input source detection to determine the input current limit according to the input source (USB or adapter). The IC sets the input current limit using Table 2 once the DP1/DM1 detection is complete.

Table 2: Input Current Limit Setting

DP1/DM 1 Detection	I <sub>IN_LMT</sub>
Floating	500mA
SDP	500mA
CDP or DCP	Set through R <sub>ILIM</sub>

b. The charge current is limited by the input voltage regulation.

Once the input voltage approaches the input voltage regulation threshold (internally preset at 4.65V), the charge current is reduced to allow priority of the system power and maintain proper regulation of the input voltage. This occurs when the input power source does not have enough capability or the voltage loss on the USB cable is too big.

4. If a certain operation state cannot be tested, an external wire can be added to connect a power source. Short DP1 and DM1 to set the DP1/DM1 detection as SDP; the input current limit is 500mA.
5. Connect USB2 and USB3 to the e-load or real smartphone. Most charge mode functions can be tested once these connections are made.

a. Input current limit

When the DC power supply has a greater current capability than the input current limit, increase the load current of the e-load. When the input current reaches this limit, the charge current decreases to keep the input current constant at the limit value.

b. Input voltage regulation

When the DC power supply has a smaller current capability than the input current limit, increase the load current of the e-load. The input power source may be insufficient to support both the charge current and system load current; this will cause the input voltage to drop. Once the voltage drops to the V<sub>IN\_REG</sub>, the charge current reduces to allow priority of the system power and keep the input voltage from dropping further.

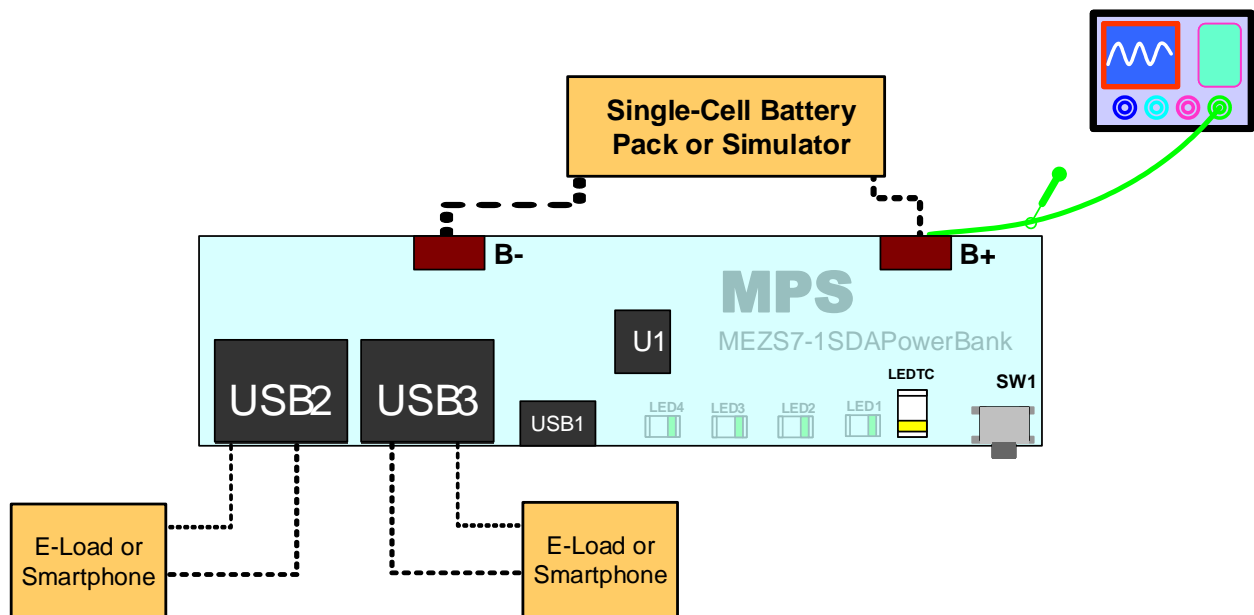

Figure 2: Set-Up for Charge Mode with System Load

**Boost Function**

1. Connect the e-load or real smartphone to SYS USB2 and USB3 on the solution module.
2. Attach the positive and negative ends of the battery to the “+” and “-” terminals, respectively. If using a battery simulator, preset the voltage to 3.8V (typical value) first.
3. Ensure the battery protection chip is enabled. If the chip is in sleep mode, the following steps are required:
  - a. Connect USB1 with a 5V input source so the IC works in charge mode to enable the battery protection chip.
  - b. Remove  $V_{IN}$  from USB1.
4. Short push SW1 from high to low for more than 1.5ms; the boost should start to work. Verify the system output current is limited at 3A.
5. Long push SW1 high to low for more than 2.5s; boost operation should shut down.
6. Double-click SW1 to turn LEDTC on or turn off.
7. Once the voltage between the “+” and “-” terminals drops below the over-discharge voltage, the battery protection chip operates in sleep mode. The boost operation cannot be enabled until the battery pack charge exceeds the over-discharge voltage. If a battery simulator is used for the test, only ramping up the battery simulator voltage will not enable the battery protection chip from sleep mode. Step 3 is still required.

**Figure 3: Set-Up for Boost Mode**

8. Remove the load from USB2 and USB3; boost operation should terminate after 16s.
9. Connect a smartphone to USB2 or USB3 when the MP2632 is in sleep mode; this enables boost operation.
10. IC operation can automatically switch to boost mode from charge mode if the input voltage at USB1 is removed.

Because the boost function is influenced by the decrease rate of the input voltage, considering the adapter’s large output capacitor, it is recommended to add a 1k $\Omega$  resistance between  $V_{IN}$  and GND.
